Key Historical Developments  
Basic Logic Circuits

# Overall Yield

If both hard and soft faults affect the yield of a circuit, the overall yield is given by the expression

$$Y = Y_H Y_S$$

# Cost Per Good Die

The manufacturing costs per good die is given by

$$C_{\text{Good}} = \frac{C_{\text{FabDie}}}{Y}$$

where  $C_{\text{FabDie}}$  is the manufacturing costs of a fab die and  $Y$  is the yield

There are other costs that must ultimately be included such as testing costs, engineering costs, etc.

# Statistics are Real!

Statistics govern what really happens throughout much of the engineering field!

**Statistics are your Friend !!!!**

You might as well know what will happen since statistics characterize what WILL happen in the presence of variability in many processes !

# Statistics Review

$$\int_{-\infty}^{\infty} f(x) dx = 1$$

$$y = \frac{x - \mu}{\sigma}$$

$$\int_{-\infty}^{\infty} f_N(y) dy = 1$$

Theorem 1: If the random variable  $x$  is normally distributed with mean  $\mu$  and standard deviation  $\sigma$ , then  $y = \frac{x - \mu}{\sigma}$  is also a random variable that is normally distributed with mean 0 and standard deviation of 1.

(Normal Distribution and Gaussian Distribution are the same)

# Many Companies Promote the Real Six-Sigma Challenge

From Wikipedia Sept 1 2021

**Six Sigma** ( $6\sigma$ ) is a set of techniques and tools for process improvement. It was introduced by American engineer [Bill Smith](#) while working at [Motorola](#) in 1986.<sup>[1][2]</sup> A six sigma process is one in which 99.99966% of all opportunities to produce some feature of a part are statistically expected to be free of defects.

# Yield at the Six-Sigma level

This is approximately 2 defects out of 1 billion parts

Would producing ICs with a yield at the six-sigma level be a good goal?

How about smart phones with defects at this level? (approx. 1.4B sold in 2020)

How about automobiles? (approx. 78 million produced in 2020)

# Yield at the Six-Sigma level

This is approximately 2 defects out of 1 billion parts

Would producing ICs with a yield at the six-sigma level be a good goal?

How about smart phones with defects at this level? (approx. 1.4B sold in 2020)

How about automobiles? (approx. 78 million produced in 2020)

# Six-Sigma or Else !!

How serious is the “or Else” in the six-sigma programs?

## Six-Sigma or Else !!

It is assumed that the performance or yield will drop, for some reason, by 1.5 sigma after a process has been established

Initial “six-sigma” solutions really expect only 4.5 sigma performance in steady-state production

Assumption : Processes of interest are Gaussian (Normal)

4.5 sigma performance corresponds to 3.4 defects in a million

Observation: Any Normally distributed random variable can be mapped to a  $N(0,1)$  random variable by subtracting the mean and dividing by the variance

# Meeting the Real Six-Sigma Challenge

Highly Statistical Concept !

# The Six-Sigma Challenge

Two-sided capability:

Long-term Capability

Tails are 6.8 parts in a million

Short-term Capability

Tail is 2 parts in a billion

**Six Sigma Performance is Very Good !!!**

Example: Determine the maximum die area if the circuit yield is to initially meet the “six sigma” challenge for hard yield defects (Assume a defect density of  $1\text{cm}^{-2}$  and only hard yield loss). Is it realistic to set six-sigma die yield expectations on the design and process engineers?

Solution:

The “six-sigma” challenge requires meeting a 6 standard deviation yield with a Normal (0,1) distribution

$$Y_{6\text{sigma}} = 2F_N(6) - 1$$

Recall:  $F_N(6) = 0.9999999980$

$$Y_{6\text{sigma}} = 0.9999999996$$

Solution cont:

$$Y_H = e^{-Ad} \quad A = \frac{-\ln(Y_H)}{d}$$

$$A = \frac{-\ln(.99999999980)}{1\text{cm}^{-2}} = 4.0\text{E} - 9\text{cm}^2 = 40\text{E}6(\text{\AA})^2$$

Consider a 20nm process with  
10x area overhead

$$A_{TRAN} = 10 * (200)^2 (\text{\AA})^2 = 4\text{E}5(\text{\AA})^2$$

$$n = \frac{40\text{E}6(\text{\AA})^2}{4\text{E}5(\text{\AA})^2} = 100$$

This is comparable to the area required to fabricate about 100 minimum-sized transistors in a state of the art 20nm process

Solution cont:

Is it realistic to set six-sigma die hard yield expectations on the design and process engineers?

The best technologies in the world have orders of magnitude too many defects to build any useful integrated circuits with die yields that meet six-sigma performance requirements !!

**Arbitrarily setting six-sigma design requirements will guarantee financial disaster !!**

Example: This was part of an article that appeared on Jan 26, 2022. The content of the article is not relevant but rather it serves as an example of use of statistics in our society

[The Washington Post](#) in 2018 reported the statistical likelihood of a public school student in the US being killed by gunfire at school was roughly 1 in 614,000,000 since 1999.

**Is this an abuse of statistics?**

# Statistics can be abused !

Many that are not knowledgeable  
incorrectly use statistics

Many use statistics to intentionally  
mislead the public

Some openly abuse statistics for financial  
gain or for manipulation purposes

Keep an open mind to separate “good”  
statistics from “abused” statistics

# Meeting the Real Six-Sigma Challenge

Six-sigma capability has almost nothing to do with optimizing profits and, if taken seriously, will likely **guarantee a financial fiasco** in most manufacturing processes

# Meeting the real Six-Sigma Challenge

Actually optimizing a process to six-sigma performance will almost always guarantee financial disaster!

**The concept of improving reliability (really profitability) is good – its just the statistics that are abused!**

# Meeting the real Six-Sigma Challenge

I got the message

# The Perception

# The Reality

- Designing for  $4.5\sigma$  or  $6\sigma$  yield variance will almost always guarantee large losses
- Yield targets should be established to optimize earnings not yield variance

# The Perception on Yield

Perception is often that goal should be to get yields as close to 100% as possible

# The Reality about Yield

- Return on improving yield when yield is above 95% is small
- Inflection point could be at 99% or higher for some designs but below 50% for others
- Cost/good die will ultimately go to  $\infty$  as yield approaches 100%

**Designers goal should be to optimize profit, not an arbitrary yield target**

## 1926 - Field Effect Semiconductor Device Concepts Patented

*Julius Lilienfeld files a patent describing a three-electrode amplifying device based on the semiconducting properties of copper sulfide. Attempts to build such a device continue through the 1930s.*

Julius E. Lilienfeld, passport photo

Polish-American physicist and inventor Julius E. Lilienfeld filed a patent in 1926, "Method and Apparatus for Controlling Electric Currents," in which he proposed a three-electrode structure using copper-sulfide semiconductor material. Today this device would be called a field-effect transistor. While working at Cambridge University in 1934, German electrical engineer and inventor Oskar Heil filed a patent on controlling current flow in a semiconductor via capacitive coupling at an electrode - essentially a field-effect transistor. Although both patents were granted, no records exist to prove that Heil or Lilienfeld actually constructed functioning devices.

These radio sets were designed to receive [amplitude modulation](#) (AM) broadcasts in the [medium wave](#) band, and were manufactured in the [United States](#) from the mid-1930s until the early 1960s<sup>[1]</sup> By

# Naming the Transistor

From the group at Bell Labs

“We have called it the transistor, T-R-A-N-S-I-S-T-O-R, because it is resistor or semiconductor device which can amplify electrical signals as they are transferred through it from input to output terminals. It is, if you will, the electrical equivalent of a vacuum tube amplifier. But there the similarity ceases. It has no vacuum, no filament, no glass tube. It is composed entirely of cold, solid substances.”

William Shockley

<http://www.time.com/time/time100/scientist/profile/shockley03.html>

## William Shockley

He fathered the transistor and brought the silicon to Silicon Valley but is remembered by many only for his noxious racial views

By GORDON MOORE

Gordon Moore

The transistor was born just before Christmas 1947 when John Bardeen and Walter Brattain, two scientists working for William Shockley at Bell Telephone Laboratories in Murray Hill, N.J., observed that when electrical signals were applied to contacts on a crystal of germanium, the output power was larger than the input. Shockley was not present at that first observation. And though he fathered the discovery in the same way Einstein fathered the atom bomb, by advancing the idea and pointing the way, he felt left out of the momentous occasion.

Shockley, a very competitive and sometimes infuriating man, was determined to make his imprint on the discovery. He searched for an explanation of the effect from what was then known of the quantum physics of semiconductors. In a remarkable series of insights made over a few short weeks, he greatly extended the understanding of semiconductor materials and developed the underlying theory of another, much more robust amplifying device — a kind of sandwich made of a crystal with varying impurities added, which came to be known as the junction transistor. By 1951 Shockley's co-workers made his semiconductor sandwich and demonstrated that it behaved much as his theory had predicted.

Not content with his lot at Bell Labs, Shockley set out to capitalize on his invention. In doing so, he played a key role in the industrial development of the region at the base of the San Francisco Peninsula. It was Shockley who brought the silicon to Silicon Valley.

In February 1956, with financing from Beckman Instruments Inc., he founded Shockley Semiconductor Laboratory with the goal of developing and producing a silicon transistor. He chose to establish this start-up near Palo Alto, where he had grown up and where his mother still lived. He set up operations in a storefront — little more than a Quonset hut — and hired a group of young scientists (I was one of them) to develop the necessary technology. By the spring of 1956 he had a small staff in place and was beginning to undertake research and development.

.... (in early 1957 a group of the key people involved with Shockley left and formed a new company named Fairchild Semiconductor ...) This new company, financed by Fairchild Camera & Instrument Corp., became the mother organization for several dozen new companies in Silicon Valley. Nearly all the scores of companies that are or have been active in semiconductor technology can trace the technical lineage of their founders back through Fairchild to the Shockley Semiconductor Laboratory. Unintentionally, Shockley contributed to one of the most spectacular and successful industry expansions in history.

*Editor's note:*

In 1963 Shockley left the electronics industry and accepted an appointment at Stanford. There he became interested in the origins of human intelligence. Although he had no formal training in genetics or psychology, he began to formulate a theory of what he called dysgenics. Using data from the U.S. Army's crude pre-induction IQ tests, he concluded that African Americans were inherently less intelligent than Caucasians — an analysis that stirred wide controversy among laymen and experts in the field alike.

(Fairchild was formed in 1957 – Moore and Noyce were 2 of 8 co-founders)

Kilby's Integrated Circuit (germanium)

<http://www.ti.com/corp/docs/kilbyctr/jackstclair.shtml>

There are few men whose insights and professional accomplishments have changed the world. Jack Kilby is one of these men. His invention of the monolithic integrated circuit - the microchip - some 45 years ago at Texas Instruments (TI) laid the conceptual and technical foundation for the entire field of modern microelectronics. It was this breakthrough that made possible the sophisticated high-speed computers and large-capacity semiconductor memories of today's information age.

Mr. Kilby grew up in Great Bend, Kansas. With B.S. and M.S. degrees in electrical engineering from the Universities of Illinois and Wisconsin respectively, he began his career in 1947 with the Centralab Division of Globe Union Inc. in Milwaukee, developing ceramic-base, silk-screen circuits for consumer electronic products.

In 1958, he joined TI in Dallas. During the summer of that year working with borrowed and improvised equipment, he conceived and built the first electronic circuit in which all of the components, both active and passive, were fabricated in a single piece of semiconductor material half the size of a paper clip. The successful laboratory demonstration of that first simple microchip on September 12, 1958, made history.

Jack Kilby went on to pioneer military, industrial, and commercial applications of microchip technology. He headed teams that built both the first military system and the first computer incorporating integrated circuits. He later co-invented both the hand-held calculator and the thermal printer that was used in portable data terminals.

Robert Noyce

<http://www.idealfinder.com/history/inventors/noyce.htm>

Robert Norton Noyce was born December 12, 1927 in Burlington, Iowa. A noted visionary and natural leader, Robert Noyce helped to create a new industry when he developed the technology that would eventually become the microchip. Noted as one of the original computer entrepreneurs, he founded two companies that would largely shape today's computer industry—Fairchild Semiconductor and Intel.

Bob Noyce's nickname was the "Mayor of Silicon Valley." He was one of the very first scientists to work in the area -- long before the stretch of California had earned the Silicon name -- and he ran two of the companies that had the greatest impact on the silicon industry: Fairchild Semiconductor and Intel. He also invented the integrated chip, one of the stepping stones along the way to the microprocessors in today's computers.

Noyce, the son of a preacher, grew up in Grinnell, Iowa. He was a physics major at Grinnell College, and exhibited while there an almost baffling amount of confidence. He was always the leader of the crowd. This could turn against him occasionally -- the local farmers didn't approve of him and weren't likely to forgive quickly when he did something like steal a pig for a college luau. The prank nearly got Noyce expelled, even though the only reason the farmer knew about it was because Noyce had confessed and offered to pay for it.

While in college, Noyce's physics professor Grant Gale got hold of two of the very first transistors ever to come out of Bell Labs. Gale showed them off to his class and Noyce was hooked. The field was young, though, so when Noyce went to MIT in 1948 for his Ph.D., he found he knew more about transistors than many of his professors.

After a brief stint making transistors for the electronics firm Philco, Noyce decided he wanted to work at Shockley Semiconductor. In a single day, he flew with his wife and two kids to California, bought a house, and went to visit Shockley to ask for a job -- in that order.

As it was, Shockley and Noyce's scientific vision -- and egos -- clashed. When seven of the young researchers at Shockley semiconductor got together to consider leaving the company, they realized they needed a leader. All seven thought Noyce, aged 29 but full of confidence, was the natural choice. So Noyce became the eighth in the group that left Shockley in 1957 and founded Fairchild Semiconductor.

Noyce was the general manager of the company and while there invented the integrated chip -- a chip of silicon with many transistors all etched into it at once. Fairchild Semiconductor filed a patent for a semiconductor integrated circuit based on the planar process on July 30, 1959. That was the first time he revolutionized the semiconductor industry. He stayed with Fairchild until 1968, when he left with Gordon Moore to found Intel.

At Intel he oversaw Ted Hoff's invention of the microprocessor -- that was his second revolution.

At both companies, Noyce introduced a very casual working atmosphere, the kind of atmosphere that has become a cultural stereotype of how California companies work. But along with that open atmosphere came responsibility. Noyce learned from Shockley's mistakes and he gave his young, bright employees phenomenal room to accomplish what they wished, in many ways defining the Silicon Valley working style was his third revolution.

It is designed to be used in test systems, terminals, billing machines, process control and random logic replacement applications. The 4004 easily interfaces with keyboards, switches, displays, A-D converters, printers and other peripheral equipment.

The CPU can directly address 4K 8-bit instruction words of program memory and 5120 bits of data storage RAM. Sixteen index registers are provided for temporary data storage. Up to 16 4-bit input ports and 16 4-bit output ports may also be directly addressed.

The 4004 is fabricated with P-channel silicon gate MOS technology.

# Basic Logic Circuits

# Basic Logic Circuits

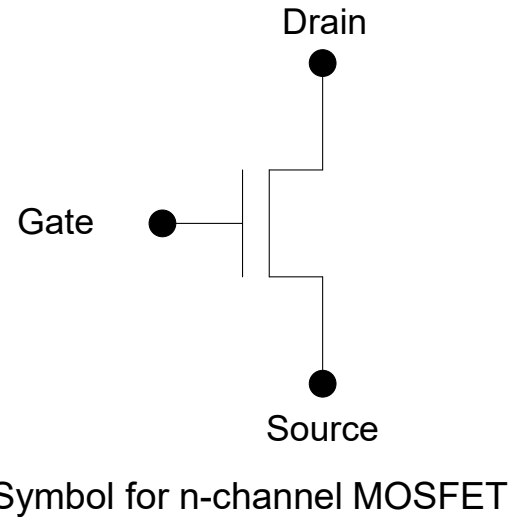

- Will present a brief description of logic circuits based upon simple models and qualitative description of processes
- Will later discuss process technology needed to develop better models
- Will even later provide more in-depth discussion of logic circuits based upon better device models

# Models of Devices

- Several models of the electronic devices will be introduced throughout the course
  - Complexity
  - Accuracy
  - Insight
  - Application
- Will use the simplest model that can provide acceptable results for any given application

Complete Symmetry in construction between Drain and Source

# MOS Transistor

## Qualitative Discussion of n-channel Operation

### Behavioral Description of Operation of n-channel MOS Transistors Created for use in Basic Digital Circuits

If  $V_{GS}$  is large, short circuit exists between drain and source

If  $V_{GS}$  is small (or negative), open circuit exists between drain and source

# Boolean/Continuous Notation:

- Voltage Axis is Continuous between  $0V$  and  $V_{DD}$
- Boolean axis is discrete with only two points

Most logic circuits characterized by the relationship between the Boolean input/output variables though these correspond to voltage intervals on the continuous voltage axis

# MOS Transistor

## Qualitative Discussion of n-channel Operation

### Equivalent Circuit for n-channel MOSFET

- Source assumed connected to (or close to) ground
- $V_{GS}=0$  denoted as Boolean gate voltage  $G=0$
- $V_{GS}=V_{DD}$  denoted as Boolean gate voltage  $G=1$
- Boolean  $G$  is relative to ground potential

This is the first model we have for the n-channel MOSFET !

Ideal switch-level model

# MOS Transistor MODEL

Equivalent Circuit for n-channel MOSFET with source at ground

Mathematical model (not dependent upon Boolean notation):

$I_D = 0$	if $V_{GS}$ is low (or negative)
$V_{DS} = 0$	if $V_{GS}$ is high

# MOS Transistor

## Qualitative Discussion of p-channel Operation

# MOS Transistor

## Qualitative Discussion of p-channel Operation

Behavioral Description of Operation of p-channel transistors created for use in basic digital circuits

If  $V_{GS}$  is large (and negative), short circuit exists between drain and source

If  $V_{GS}$  is small (near 0 or positive), open circuit exists between drain and source

# MOS Transistor

## Qualitative Discussion of p-channel Operation

### Equivalent Circuit for p-channel MOSFET

- Source assumed connected to (or close to) positive  $V_{DD}$
- $V_{GS}=0$  denoted as Boolean gate voltage  $G=1$
- $V_{GS}=-V_{DD}$  denoted as Boolean gate voltage  $G=0$
- Boolean  $G$  is relative to ground potential

This is the first model we have for the p-channel MOSFET !

# MOS Transistor MODEL

Equivalent Circuit for p-channel MOSFET with Source at VDD

Mathematical model (not dependent upon Boolean notation):

$I_D = 0$  if  $|V_{GS_p}|$  is small or  $V_{GS_p}$  is positive

$V_{DS} = 0$  if  $|V_{GS_p}|$  is large

# MOS Transistor

## Comparison of Operation

Source assumed connected  
to (or close to) ground

Source assumed connected to (or close to) positive  $V_{DD}$   
and Boolean  $G$  at gate is relative to ground

# Complete Logic Family

Family of n-input NOR gates forms a complete logic family

Family of n-input NAND gates forms a complete logic family

Having both NAND and NOR gates available is a luxury

**Can now implement any combinational logic function !!**

**If add one flip flop, can implement any Boolean system !!**

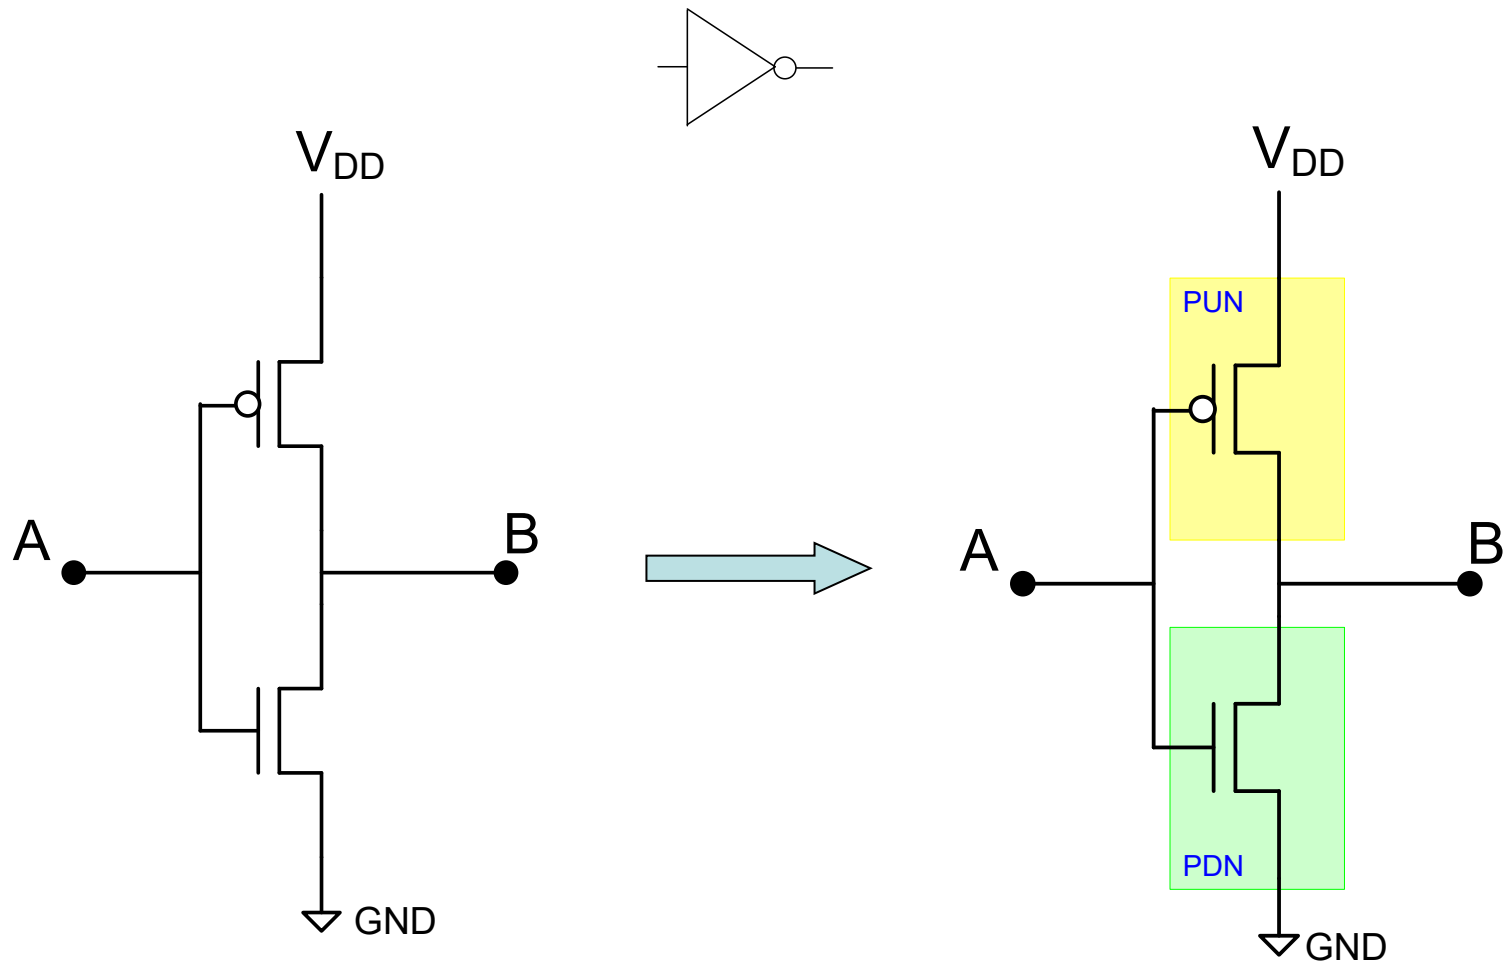

Flip flops easy to design but will discuss sequential logic systems later

# Other logic circuits

- Other methods for designing logic circuits exist
- Insight will be provided on how other logic circuits evolve
- Several different types of logic circuits are often used simultaneously in any circuit design

# Pull-up and Pull-down Networks

PU network comprised of p-channel device and “tries” to pull B to  $V_{DD}$  when conducting  
PD network comprised of n-channel device and “tries to pull B to  $GND$  when conducting  
One and only one of these networks is conducting at the same time (to avoid contention)

# Pull-up and Pull-down Networks

In these circuits, the PUN and PDN have the 3 interesting characteristics

1. PU network comprised of p-channel devices
2. PD network comprised of n-channel devices
3. One and only one of these networks is conducting at the same time

What are  $V_H$  and  $V_L$ ?

What is the power dissipation?
