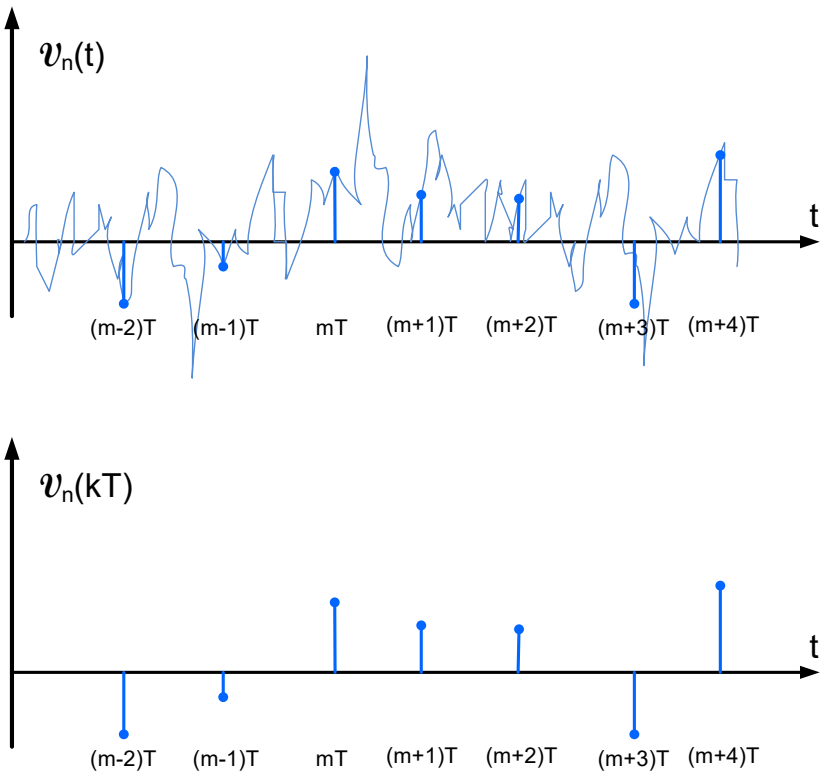
- SC Filters

Review from Last Lecture

Sample and Hold Circuits



$v_n(mT)$ for each m is a random variable with some distribution function

This distribution function is independent of m (i.e. the variables are identically distributed)

Assume μ_n is the mean and σ_n is the standard deviation of this random variable

What is the relationship, if any, between $v_{n_{RMS}}$ and $\hat{v}_{RMS}$

Review from Last Lecture

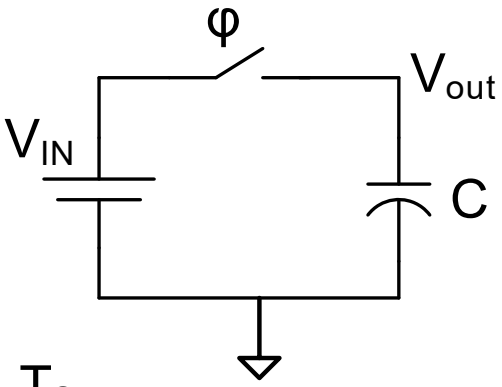
Theorem 1 If $v(t)$ is a continuous-time zero-mean noise source and $\langle v(kT) \rangle$ is a sampled version of $v(t)$ sampled at times T, 2T, …. then the RMS value of the continuous-time waveform is the same as that of the sampled version of the waveform. This can be expressed as $v_{RMS} = \hat{v}_{RMS}$

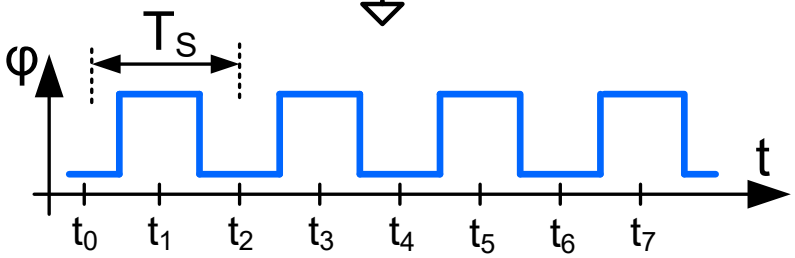
Theorem 2 If $v(t)$ is a continuous-time zero-mean noise signal and $\langle v(kT) \rangle$ is a sampled version of $v(t)$ sampled at times T, 2T, …. then the standard deviation of the random variable $v(kT)$, denoted as $\sigma_{\hat{V}}$ satisfies the expression $\sigma_{\hat{V}} = v_{RMS} = \hat{v}_{RMS}$

From Theorem 1 we obtain the RMS value of the switched capacitor sampler

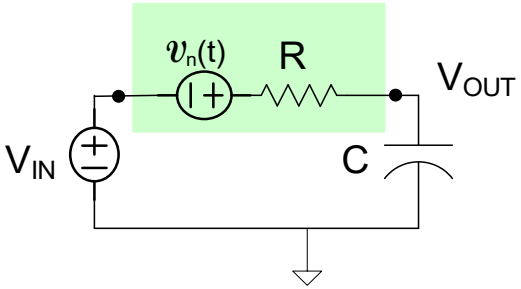
Review from Last Lecture

Sample and Hold Circuits

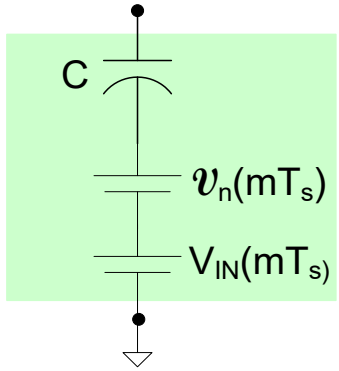




$$v_{n_{RMS}} = \sqrt{\int_{f=0}^{\infty} S_{V_{OUT}}\,df} = \sqrt{\frac{kT}{C}}$$



Track mode



Hold mode

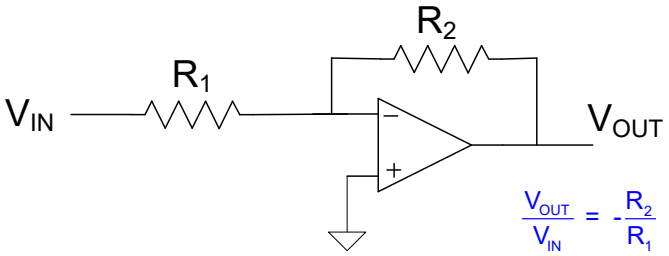
$$v_{n_{RMS}} = \sqrt{\frac{kT}{C}}$$

k: Boltzmann's constant
T: temperature in Kelvin

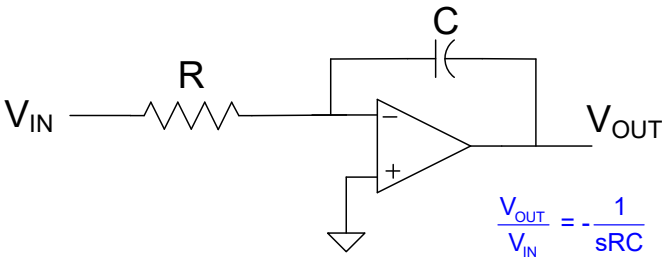
RMS noise at output of basic SC S/H is independent of R but dependent upon C

Review from Last Lecture

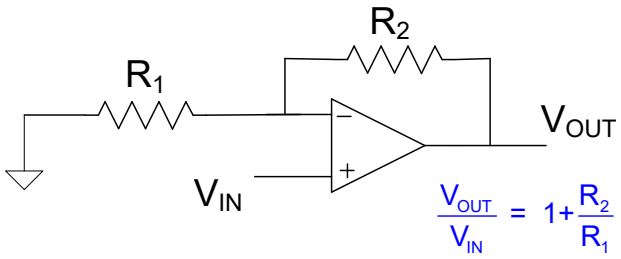
Some of the most basic and widely used analog circuits



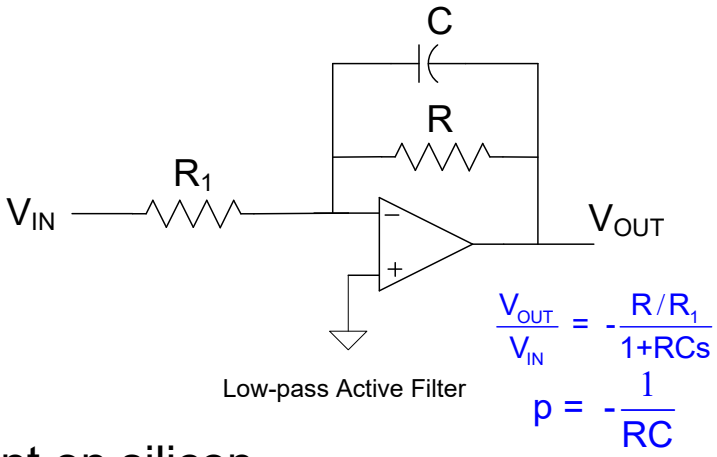
Inverting Amplifier



Inverting Integrator



Noninverting Amplifier



Low-pass Active Filter

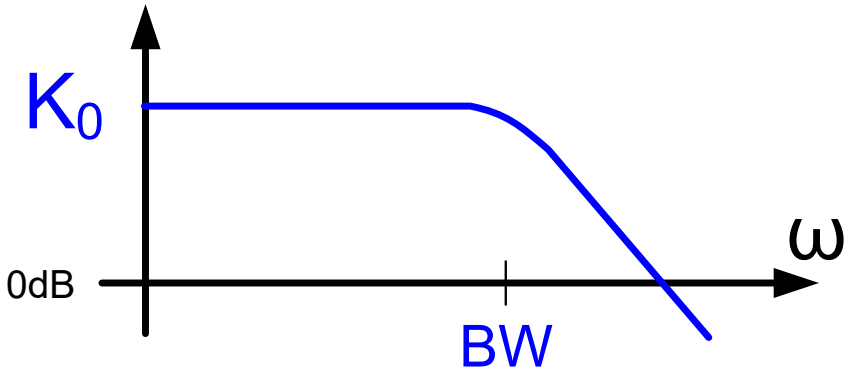
Not practical to implement on silicon

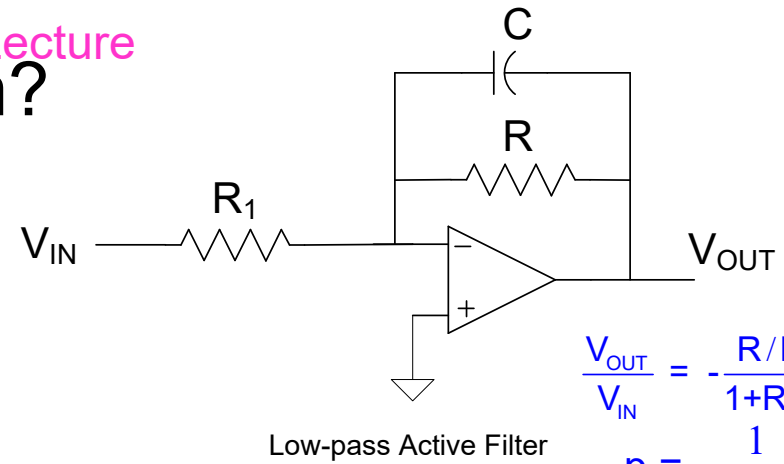
- Area for R too big
- Area for C too big
- Accuracy of I_0 and p too poor

But ratio accuracy can be very good (0.1% or better with good layout and appropriate area)

Review from Last Lecture

How bad is the problem?





Low-pass Active Filter

$$\frac{V_{OUT}}{V_{IN}} = -\frac{R/R_1}{1+RCs}$$

$$p = -\frac{1}{RC}$$

$$K_0 = 1+\frac{R_2}{R_1}$$

$$BW_{rad/sec} = -p = \frac{1}{RC}$$

Assume |p|=2π•1000 and pole accuracy needed is 0.1%

Process tolerance on R and C is about ±20%

R□=20Ω/□ and Cd=1pF/μ² (approximately)

If R=1KΩ, require 1000/20=50 squares

$$\frac{1}{RC} = 2000\pi \qquad C = \frac{1}{R\bullet 2000\pi} \qquad C = \frac{1}{1000\bullet 2000\pi} = 0.159\mu F$$

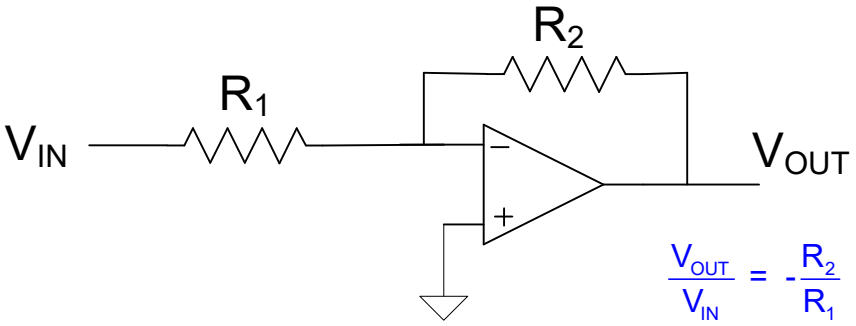
$$A_C = \frac{C}{C_D} = \frac{0.159\mu F}{1fF/\mu^2} = 1.59\times 10^8\,\mu^2 \simeq 1.6cm^2$$

Pole tolerance ±40%

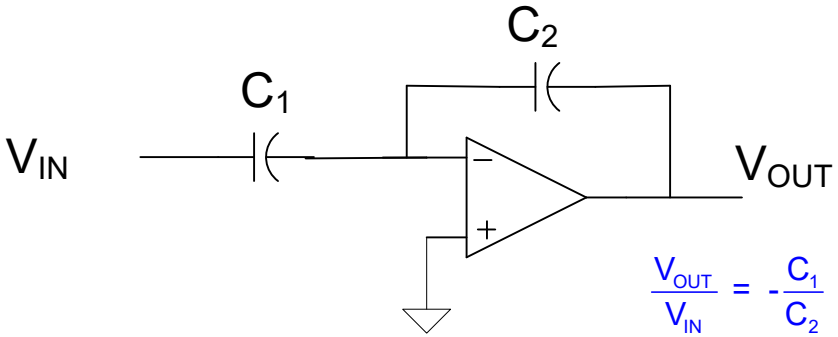
Both are orders of magnitude unacceptable !

Review from Last Lecture

An amplifier alternative ?



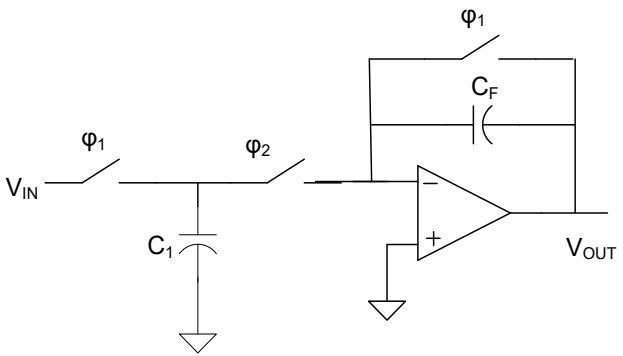
Inverting Amplifier

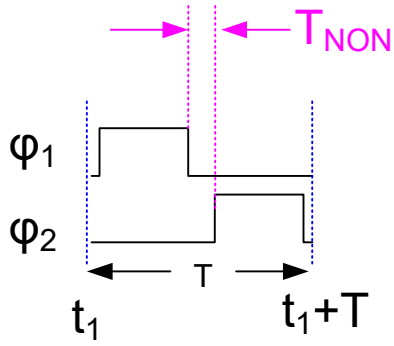


Inverting Amplifier

- Capacitor version is area effective and can have very good accuracy
- The node between C_1 and C_2 is a floating node if the Op Amp has a MOS differential pair at the input
- But if we get any charge on the intermediate node there is no way to get it off

An amplifier alternative ?:





Φ_1 and Φ_2 are nonoverlapping clocks

During Φ_1

C_1 is charged to V_{IN} and stores charge $Q_1=C_1V_{IN}$

C_F is discharged and $V_{OUT}=0$

During Φ_2

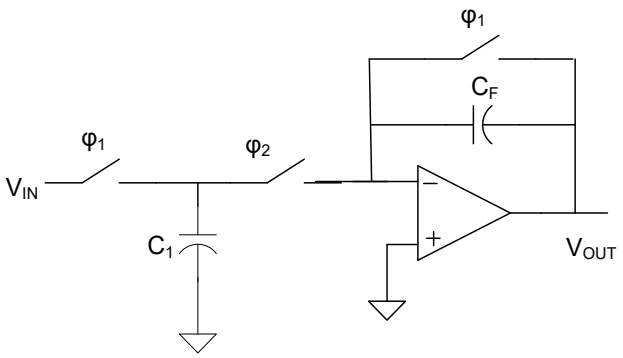
C_1 is discharged but charge is transferred to C_F

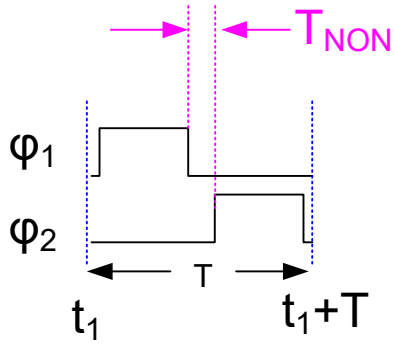
$Q_2=-Q_1$ and $V_{OUT}=Q_2/C_F$

Substituting for Q_1 we obtain $V_{OUT} = -\frac{C_1}{C_F} V_{IN}$

Serves as a voltage amplifier with output valid during φ_2

An amplifier alternative !





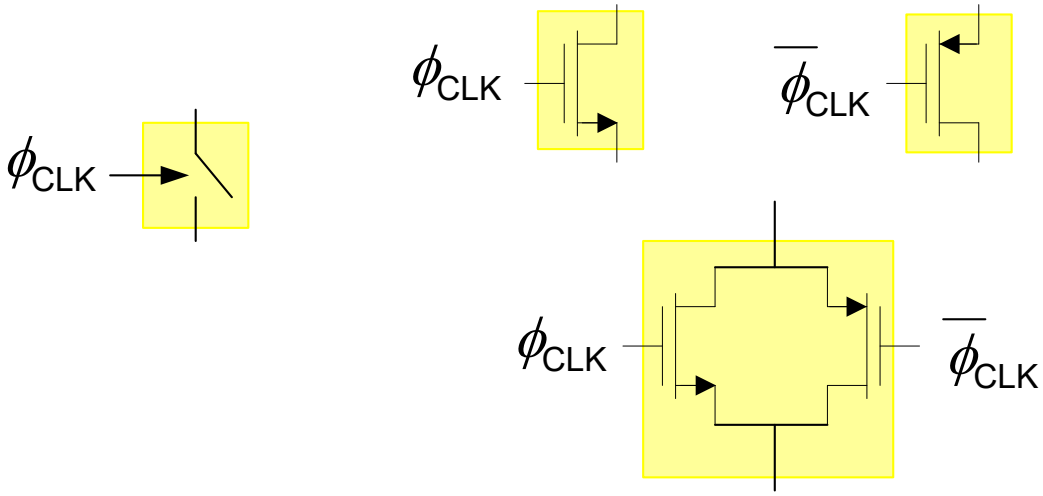
Φ_1 and Φ_2 are nonoverlapping clocks

$$V_{OUT} = -\frac{C_1}{C_F} V_{IN}$$

- Many applications only need amplifier output at discrete points in time
- Accuracy can be very good
- Area can be very small

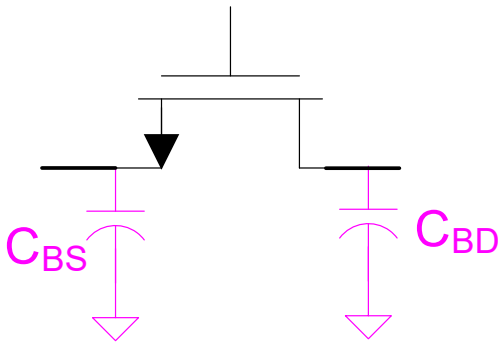
But, what about the switches?

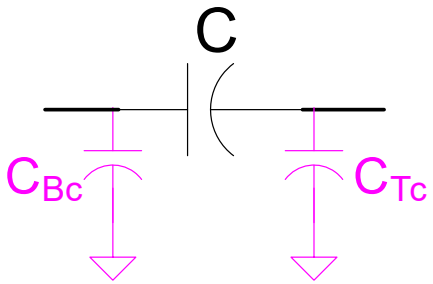
Switches for SC Circuits



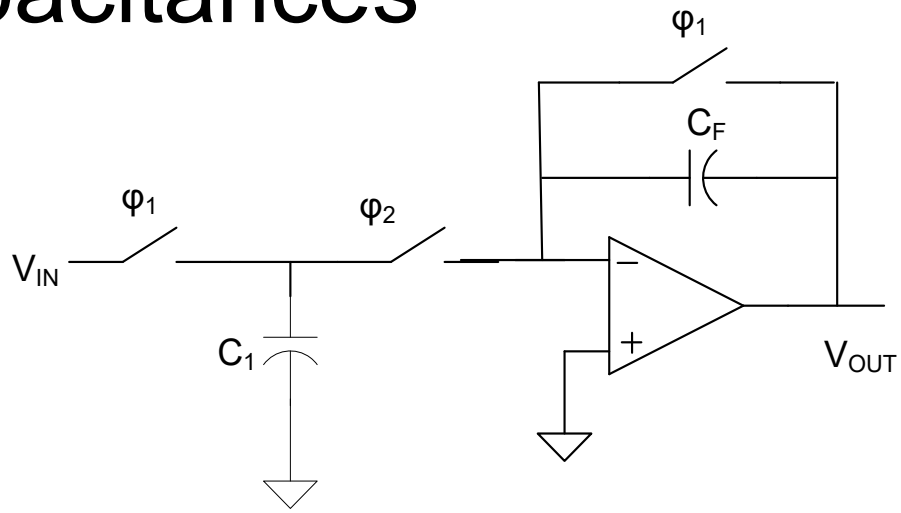
- Often a single MOS transistor is adequate (either n-ch or p-ch)
- Sometimes need transmission-gate switch (parallel n-ch and p-ch)
- Switches work very well and can be very small but must manage their R_{ON}

Parasitic Capacitances





?



3 switches and 2 capacitors

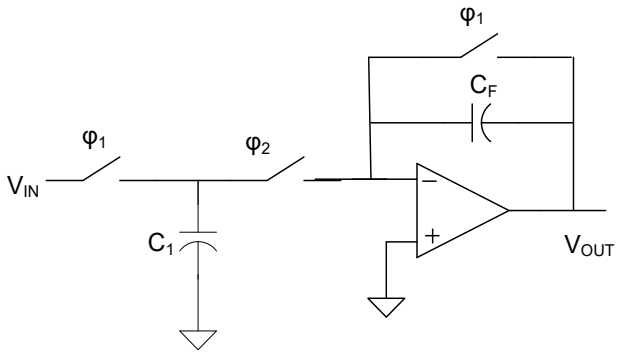
10 parasitic capacitances!

Some of parasitic capacitances may be several percent of the size of C_1 and C_F

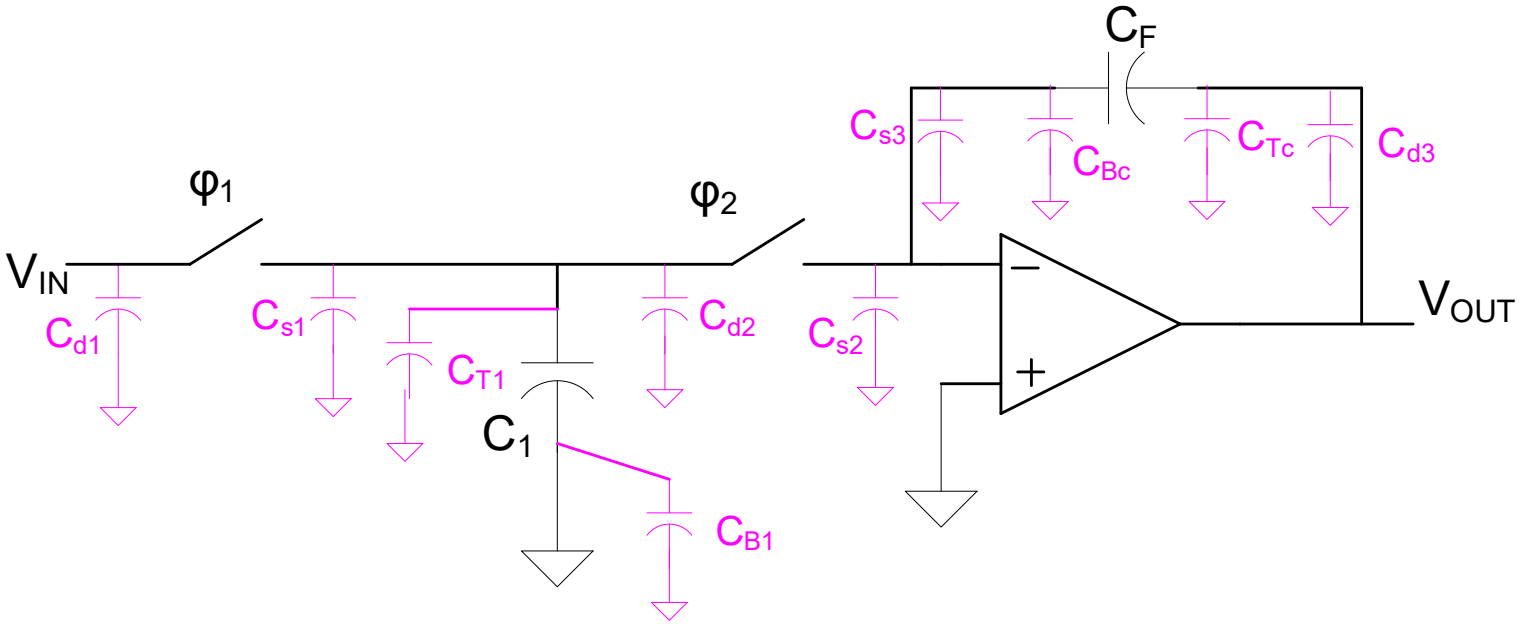
And parasitic capacitors do not match very well

And parasitic capacitances may be highly nonlinear (junction capacitors)

Parasitic Capacitances

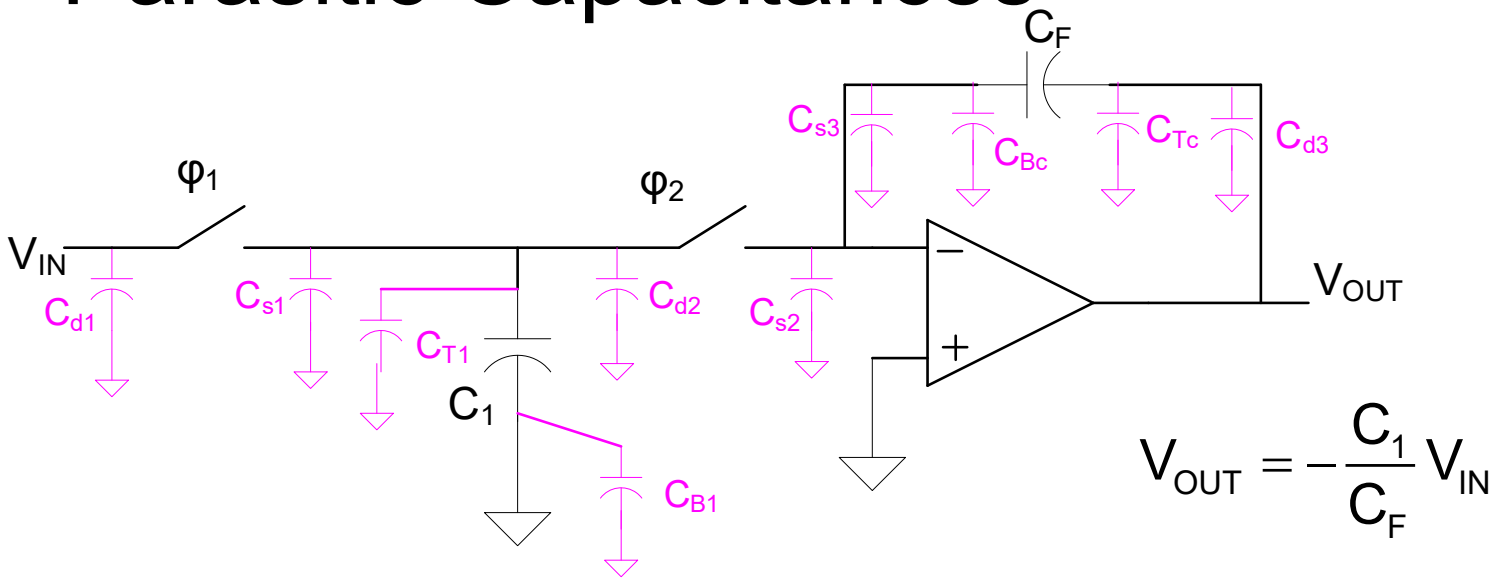


Ideally $V_{OUT} = -\frac{C_1}{C_F} V_{IN}$



10 parasitic capacitances!

Parasitic Capacitances



C_1/C_F can be very precisely controlled with appropriate layout and area allocation

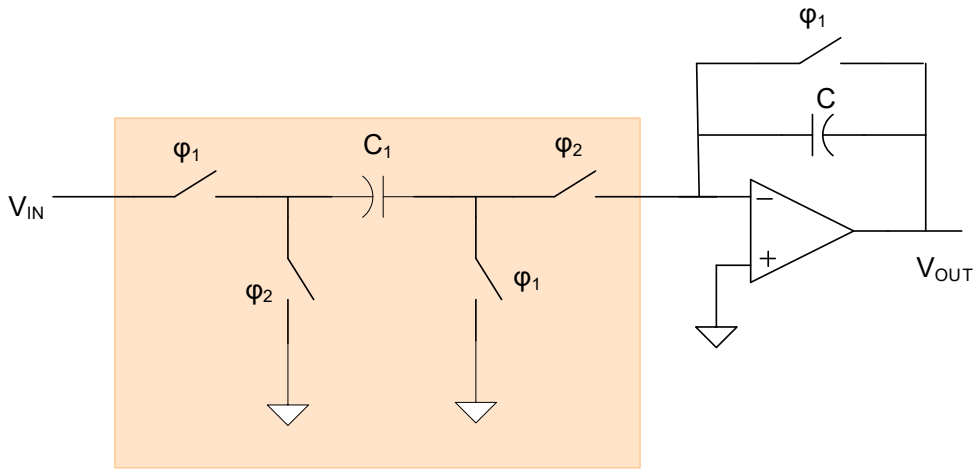
If op amp is ideal, C_{d1}, C_{B1},C_{s2},C_{s3},C_{Bc},C_{Tc} and C_{d3} do not affect charge transfer !

But C_{s1},C_{T1},C_{d2} are all in parallel with C_1 and all transfer charge

$$V_{OUT} = -\frac{C_1 + (C_{s1} + C_{T1} + C_{d2})}{C_F} V_{IN}$$

Parasitic capacitances not accurately controlled and dramatically degrade matching!

Stray Insensitive SC Amplifiers

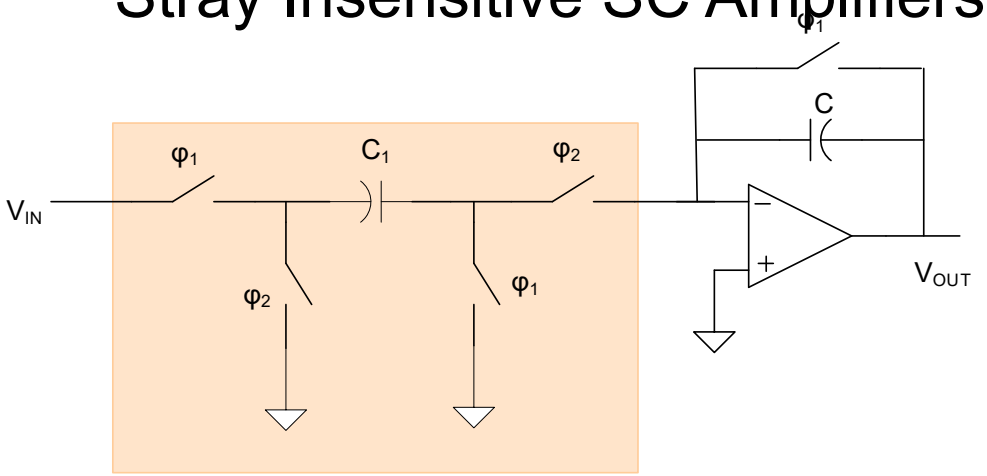


Noninverting

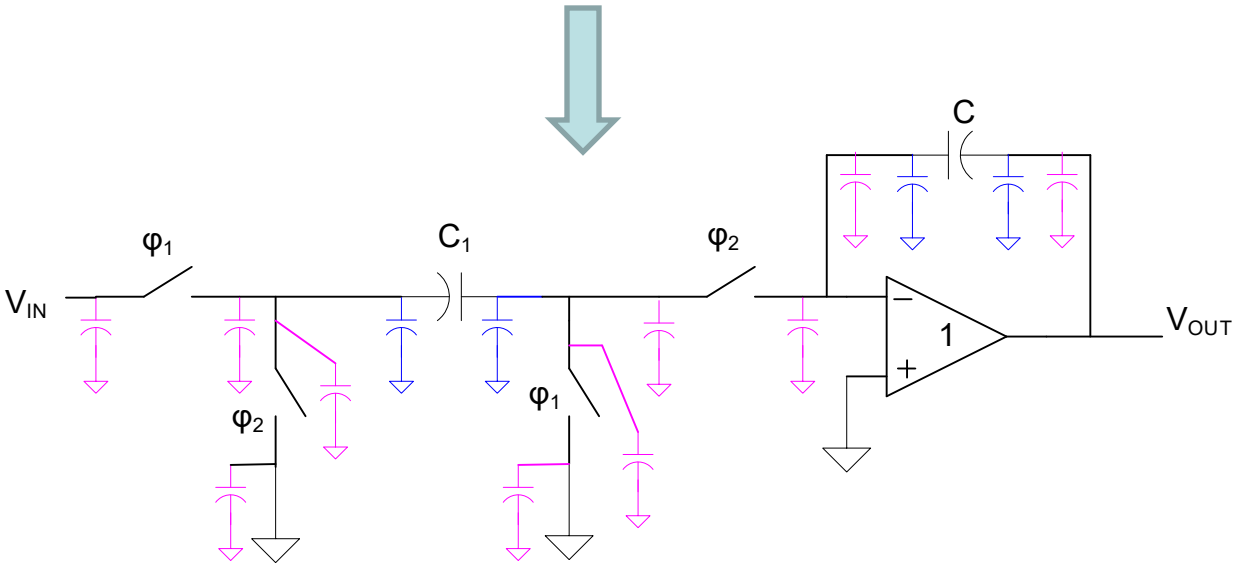
Another SC Amplifier with even more switches !

Increased to 14 diffusion parasitic capacitances

Stray Insensitive SC Amplifiers

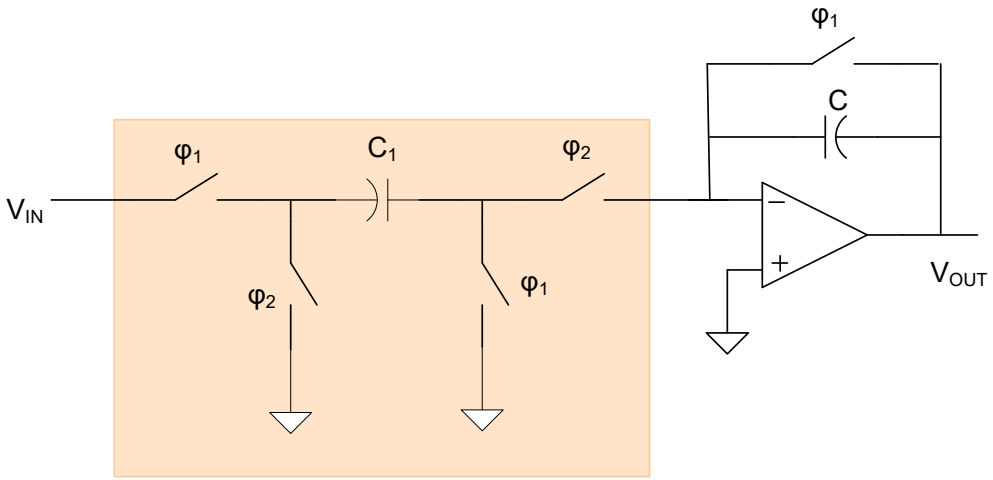


Noninverting



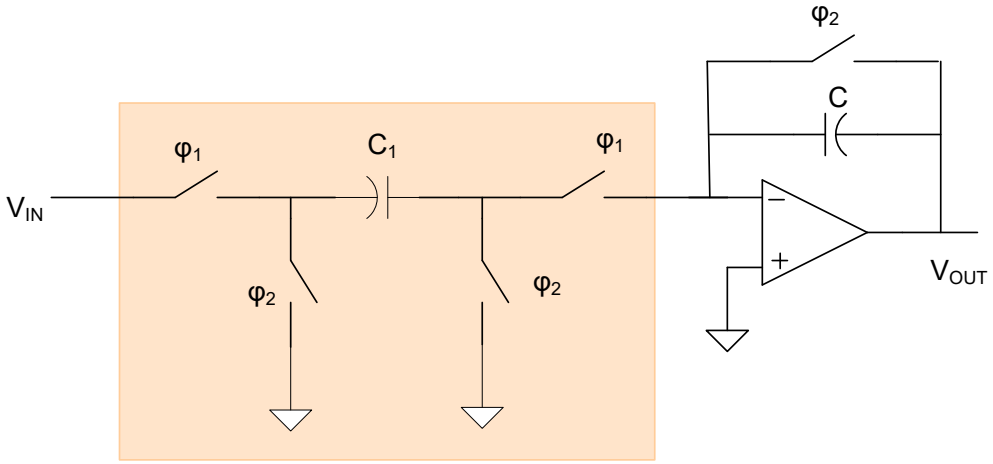
Can show that all 14 diffusion parasitic capacitances do not affect gain !!

Stray Insensitive SC Amplifiers



Noninverting

$$\frac{V_{OUT}}{V_{IN}} = \frac{C_1}{C_2}$$

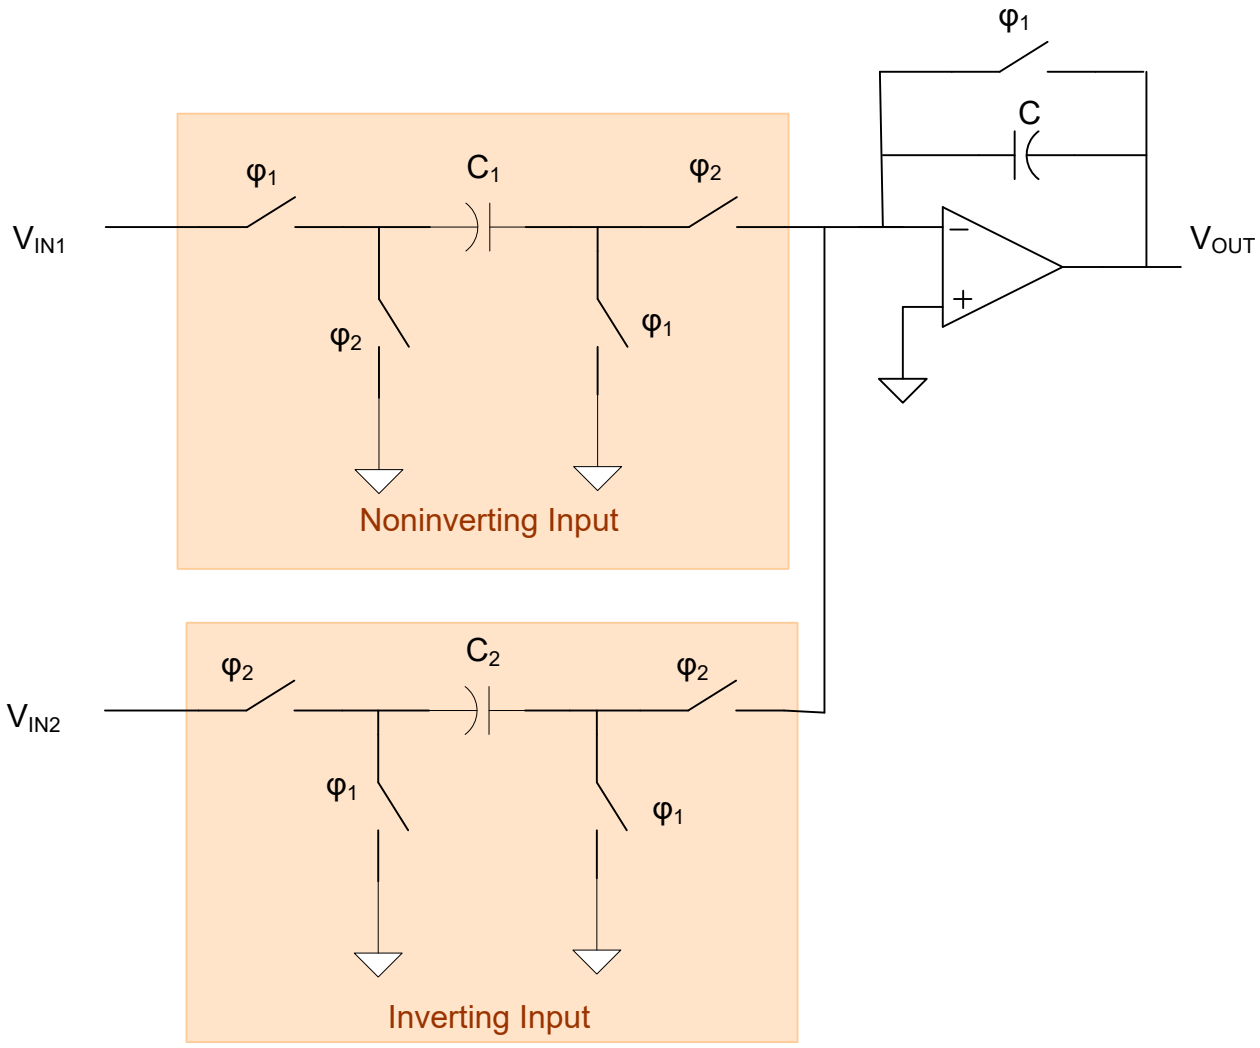


Ininverting

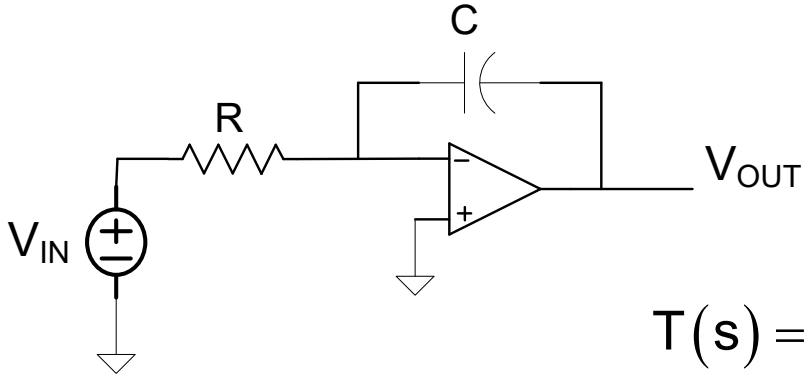
$$\frac{V_{OUT}}{V_{IN}} = -\frac{C_1}{C_2}$$

Can show that all diffusion parasitic capacitances do not affect gain
Gain can be accurately controlled !

Summing amplifier inputs either inverting or noninverting can be easily obtained



Consider the Basic Integrator



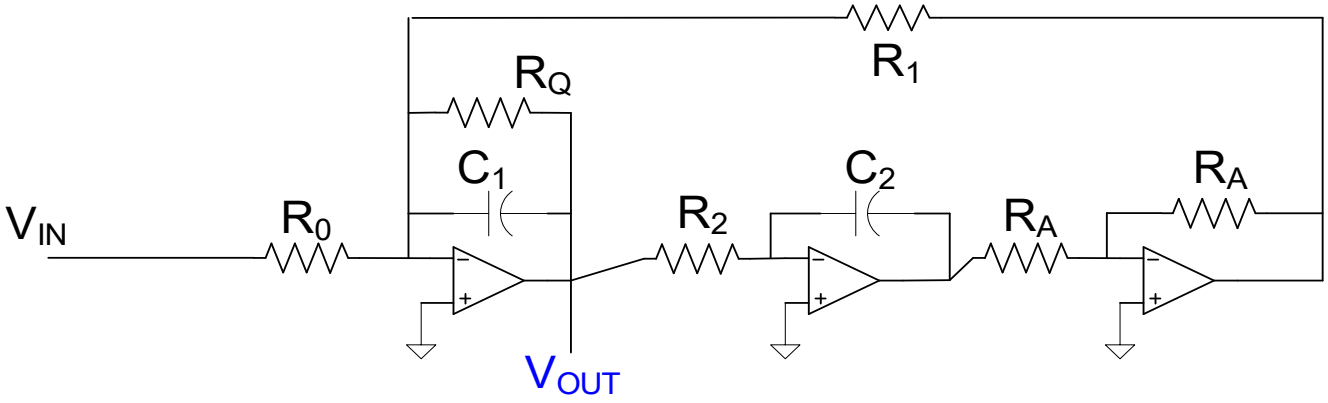
$$T(s) = -\frac{1}{RCs}$$

$$I_0 = \frac{1}{RC}$$

Key performance of integrator (and integrator-based filters) is determined by the integrator time constant I_0

Precision of time constants of a filter invariably determined by precision of I_0

Integrator-Based Filters:

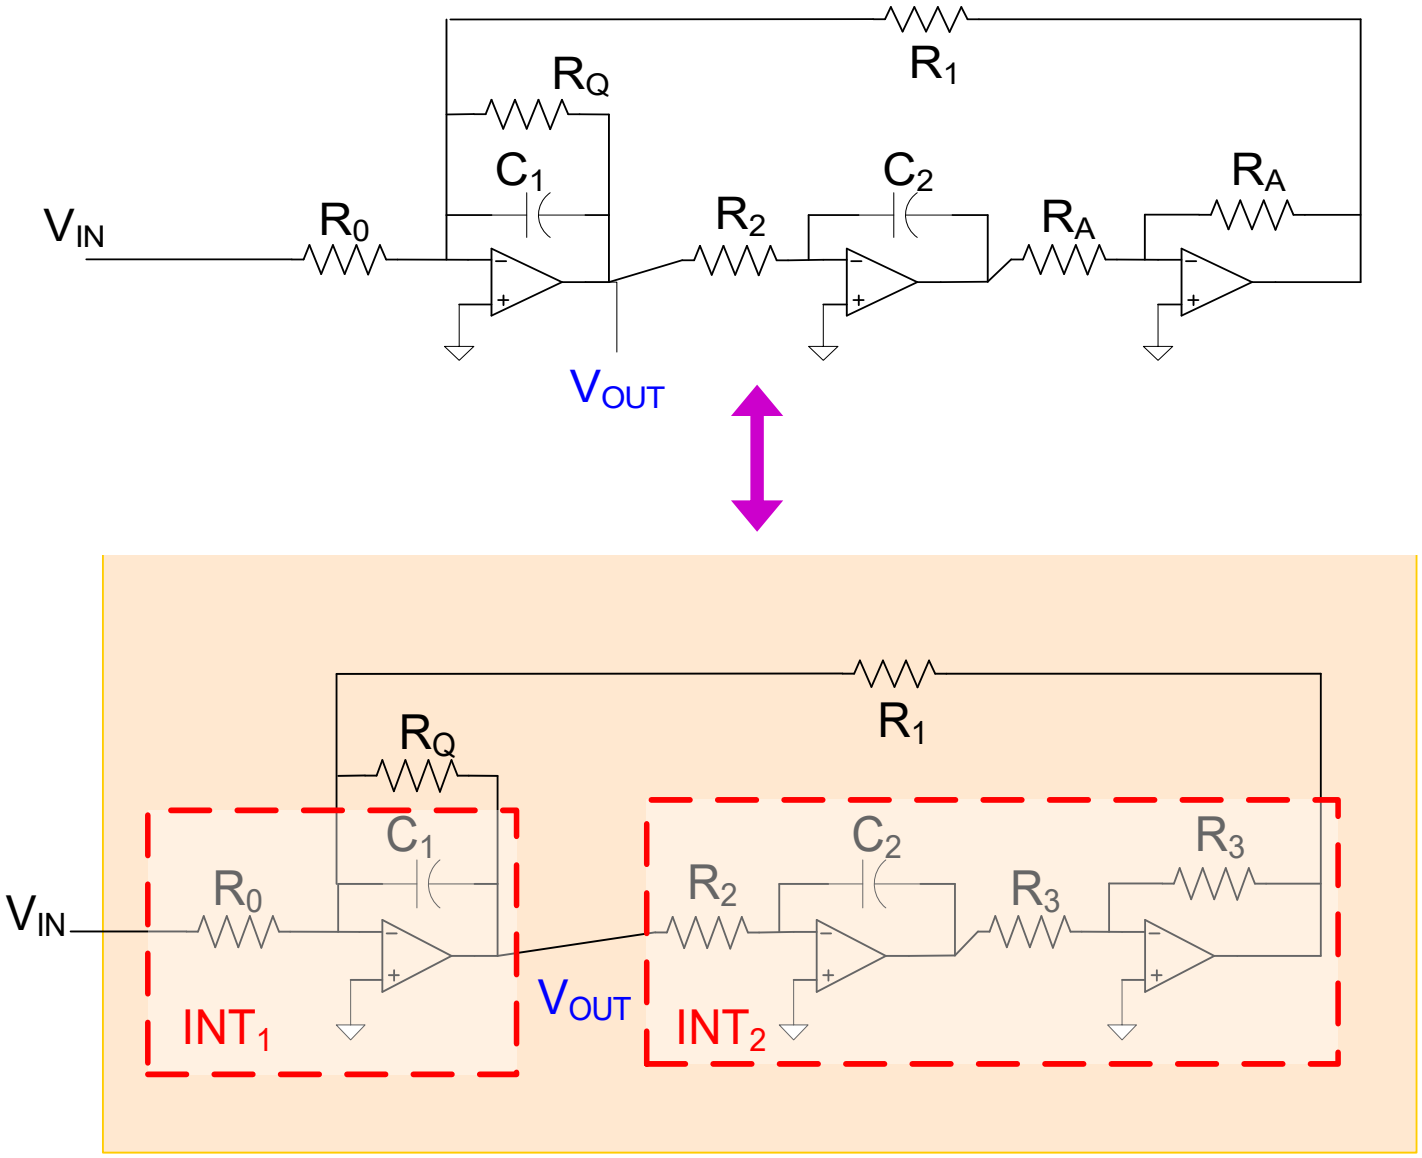


$$\frac{V_{OUT}}{V_{IN}} = T(s) = -\frac{1}{R_0 C_1} \frac{s}{s^2 + s\left(\frac{1}{R_Q C_2}\right) + \frac{1}{R_1 R_2 C_1 C_2}}$$

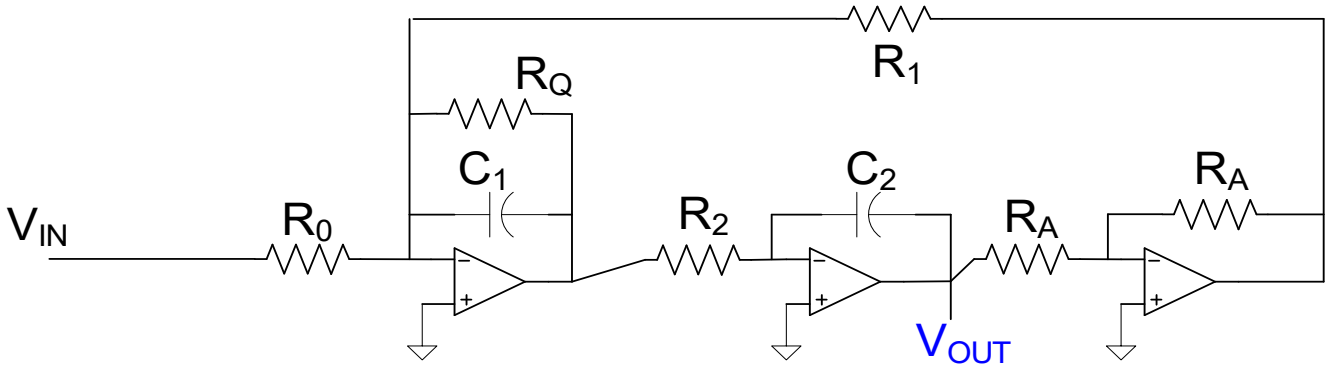
Second-order Bandpass Filter

Denote as a two-integrator-loop structure

Integrator-Based Filters:



Integrator-Based Filters:



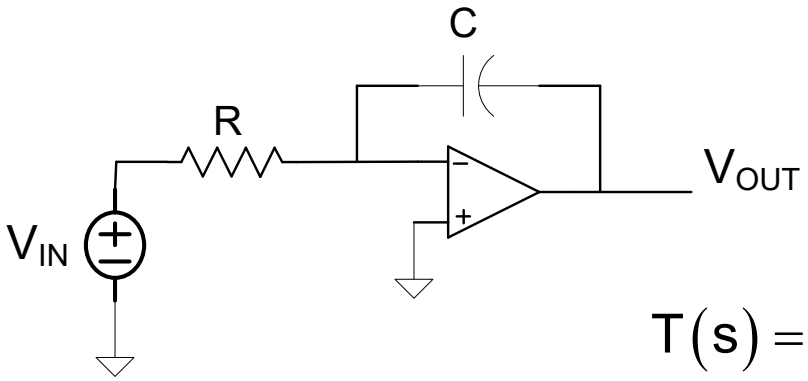
$$\frac{V_{OUT}}{V_{IN}} = T(s) = -\frac{1}{R_0 C_1} \frac{\frac{1}{R_2 C_2}}{s^2 + s\left(\frac{1}{R_Q C_2}\right) + \frac{1}{R_1 R_2 C_1 C_2}}$$

Second-order Lowpass Filter

Denote as a two-integrator-loop structure

- Any filter transfer function can be implemented with integrators and summers
- Some of the best known filter structures are based upon integrators and summers
- Accuracy of RC products is critical in the design of good filters

Consider the Basic Integrator



$$T(s) = -\frac{1}{RCs}$$

$$I_0 = \frac{1}{RC}$$

Accurate control of I_0 is required to build good filters !

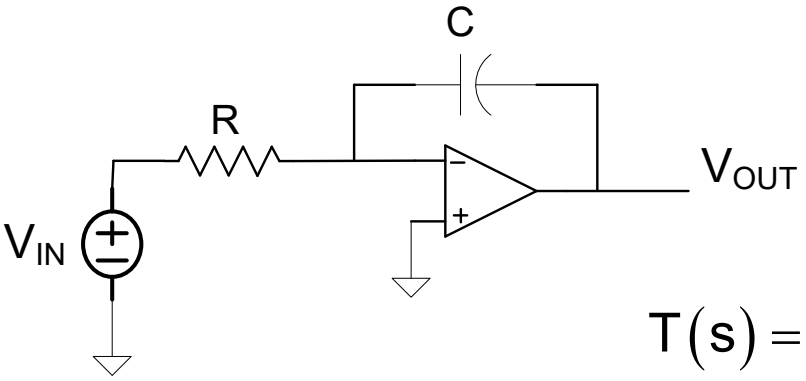
1. Accuracy of R and C difficult to accurately control – particularly in integrated applications (often 2 or 3 orders of magnitude to variable)

2. Size of R and C unacceptably large if I_0 is in audio frequency range (2 or 3 orders of magnitude too large)

3. Amplifier GB limits performance

Appears to be Incredible Challenge to Building Filters on Silicon!

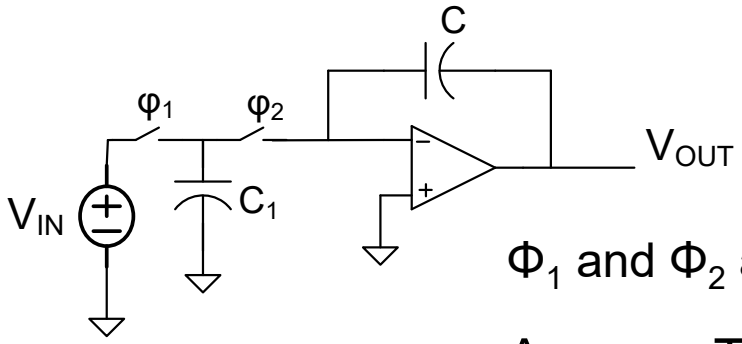
Integrator Design Issues



$$T(s) = -\frac{1}{RCs}$$

$$I_0 = \frac{1}{RC}$$

Consider:

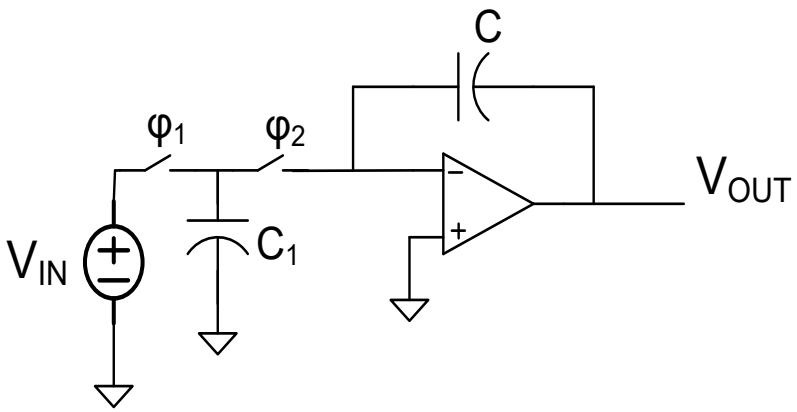


Φ_1 and Φ_2 are complimentary nonoverlapping clocks

Assume $T_{CLK} << T_{SIG}$

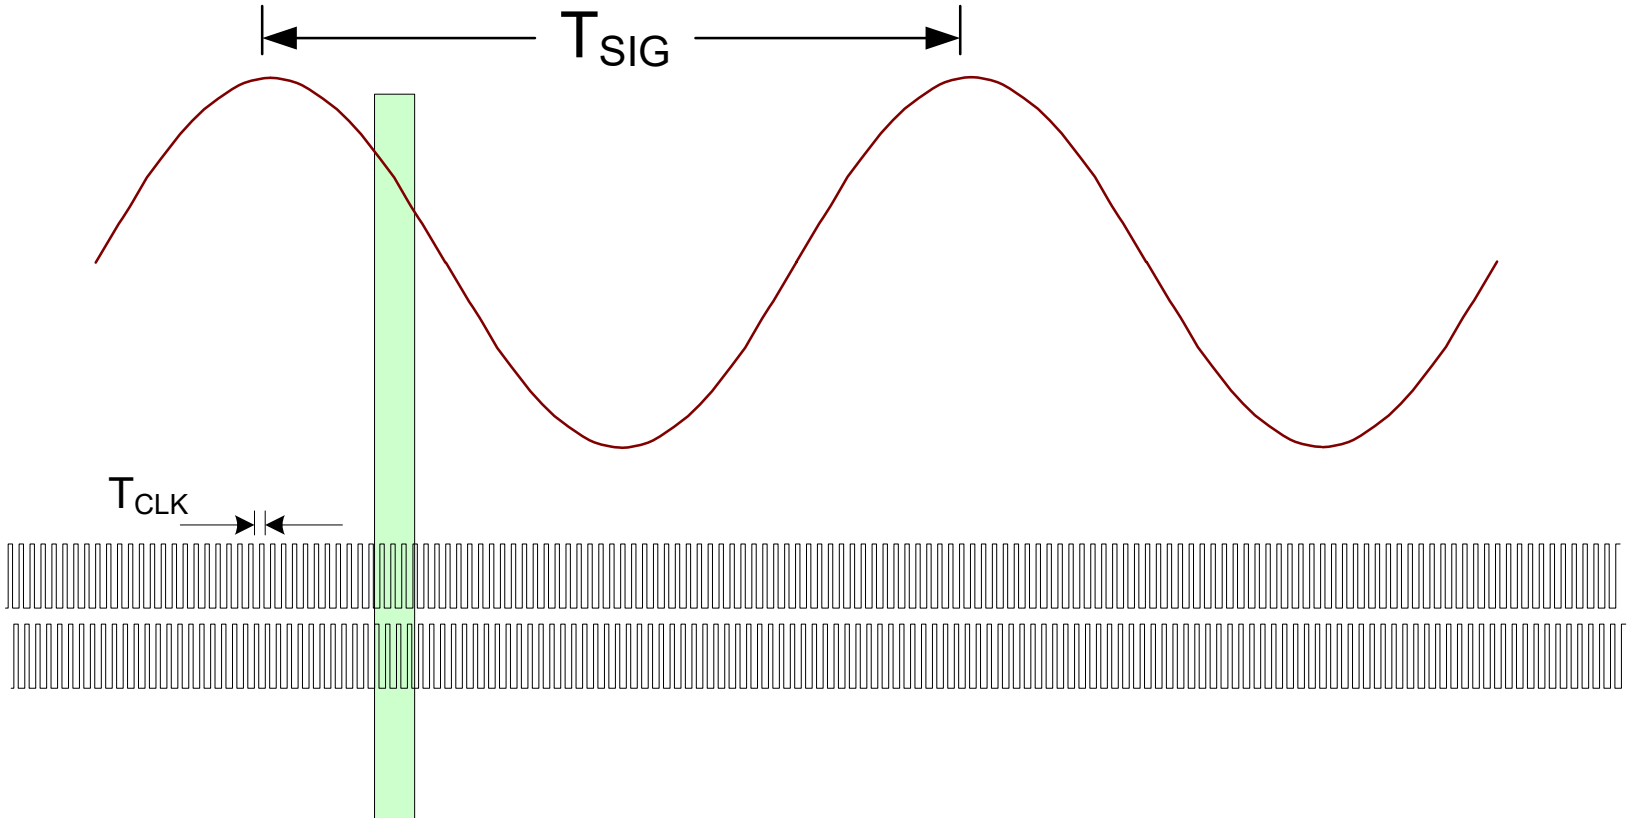
Termed a switched-capacitor circuit

Consider the Switched-Capacitor Circuit

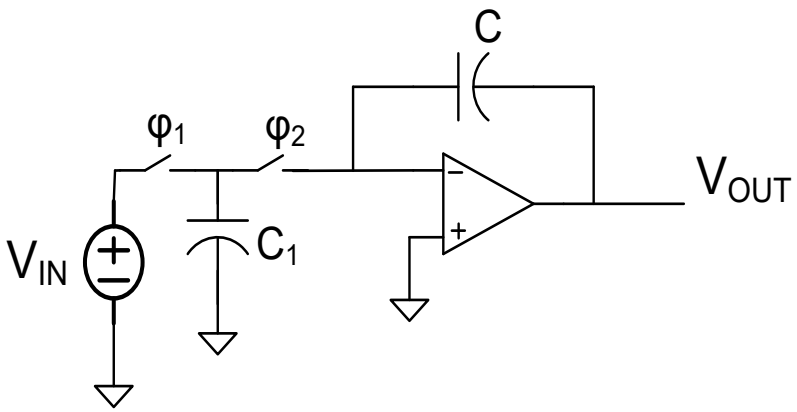


Assume $T_{CLK} << T_{SIG}$

Φ_1 and Φ_2 are complimenary nonoverlapping clocks

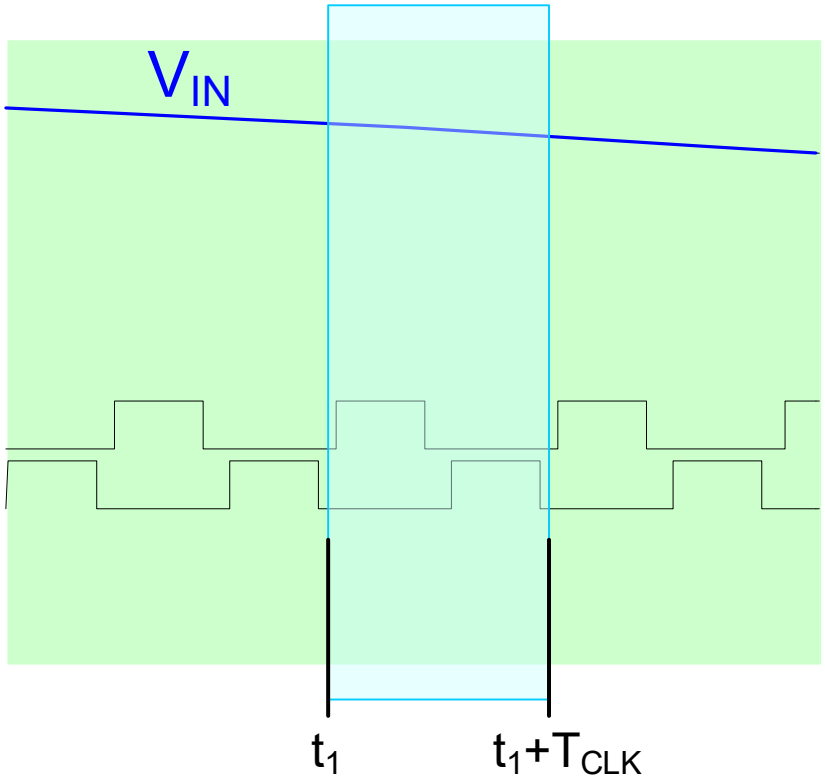


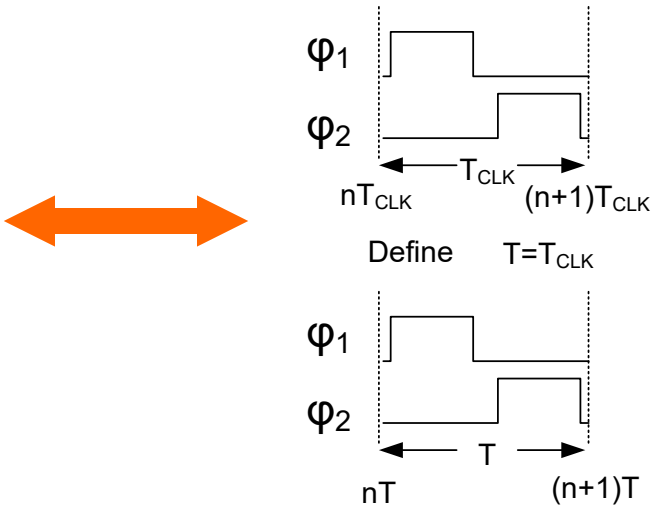
Consider the Switched-Capacitor Circuit



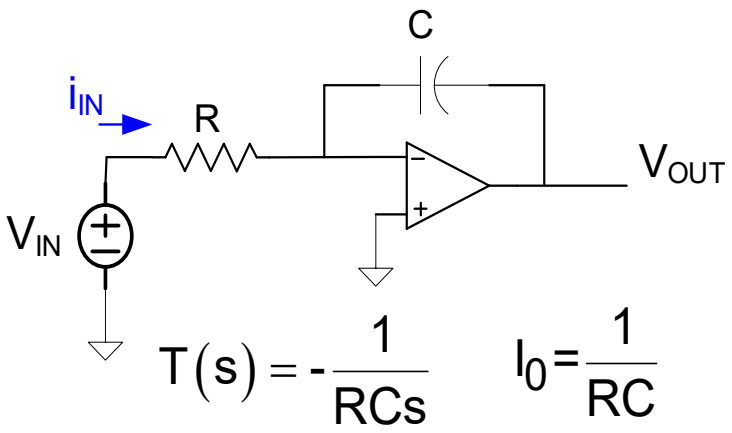
Assume $T_{CLK} << T_{SIG}$

Φ_1 and Φ_2 are complimenary nonoverlapping clocks

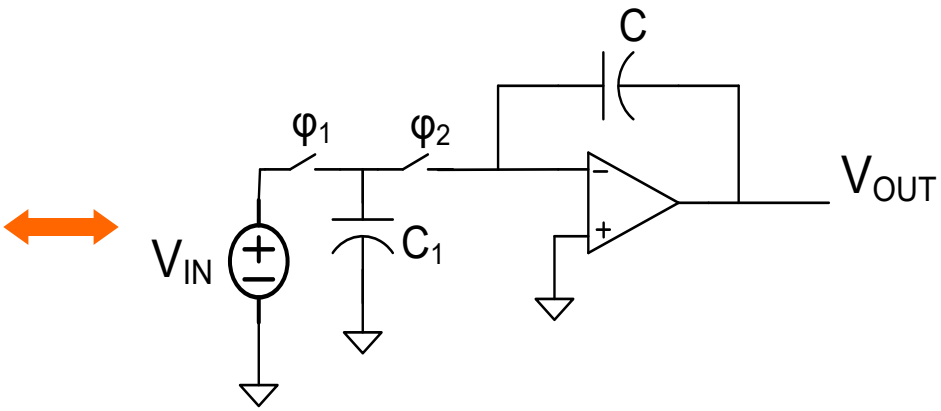




Compare the performance of the following two circuits



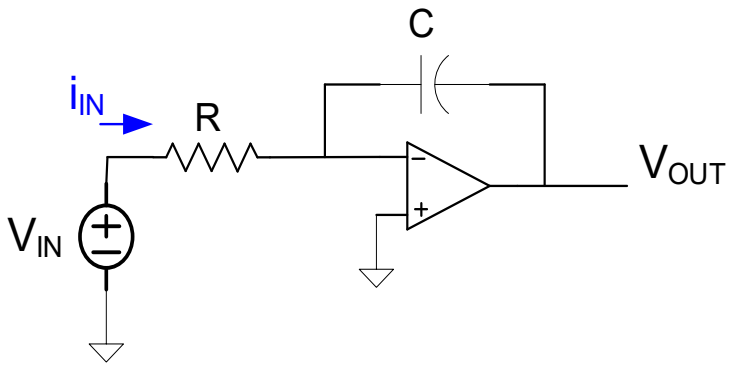
$$T(s) = -\frac{1}{RCs} \qquad I_0 = \frac{1}{RC}$$



Consider the charge transferred to the feedback capacitor for both circuits in an interval of length T_{CLK} at arbitrary time t_1

For the RC circuit:

$$Q_{RC} = \int_{t_1}^{t_1+T_{CLK}} i_{in}(t)\,dt$$



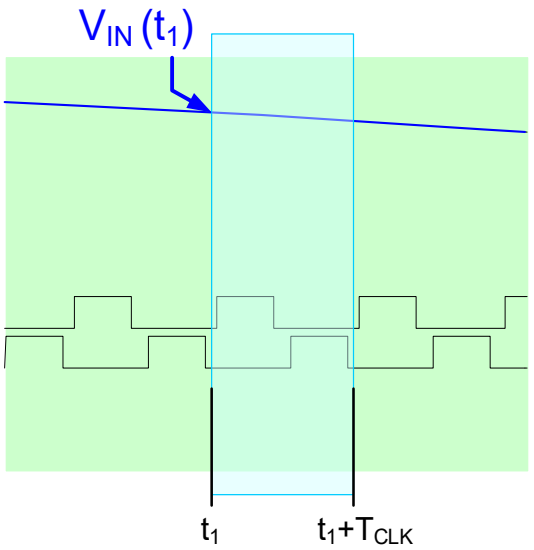
$$Q_{RC} = \int_{t_1}^{t_1+T_{CLK}} \frac{V_{in}(t)}{R}\,dt$$

Since V_{in} changes slowly assume input is constant over one clock period

$$Q_{RC} \simeq \int_{t_1}^{t_1+T_{CLK}} \frac{V_{in}(t_1)}{R}\,dt$$

$$Q_{RC} \simeq \left[\frac{V_{in}(t_1)}{R}\right] \int_{t_1}^{t_1+T_{CLK}} 1\,dt$$

$$Q_{RC} \simeq \left[\frac{V_{in}(t_1)}{R}\right] T_{CLK}$$



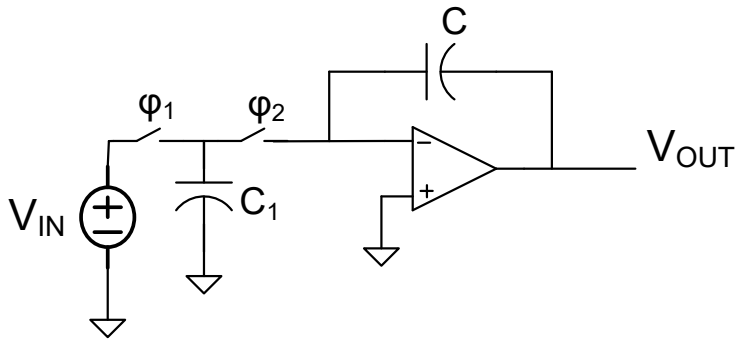
Consider the charge transferred to the feedback capacitor for both circuits in an interval of length T_{CLK} at time t_1

For the RC circuit:

$$Q_{RC} \simeq \left[\frac{V_{in}(t_1)}{R} \right] T_{CLK}$$

Observe that a resistor "transfers" charge proportional to V_{in} in a short interval of T_{CLK}

For the SC circuit



$$Q_{C1} = C_1 V_{in}\left(t_1 + \frac{T_{CLK}}{2} - \varepsilon\right)$$

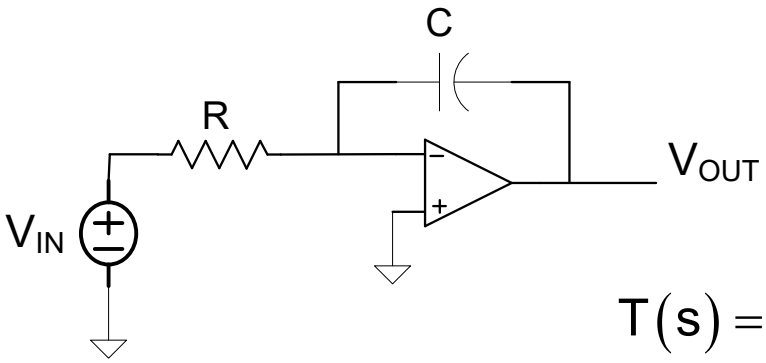
Since $V_{in}(t)$ is slowly varying

$$Q_{C1} \simeq C_1 V_{in}(t_1)$$

But this is the charge that will be transferred to C during phase Φ_2

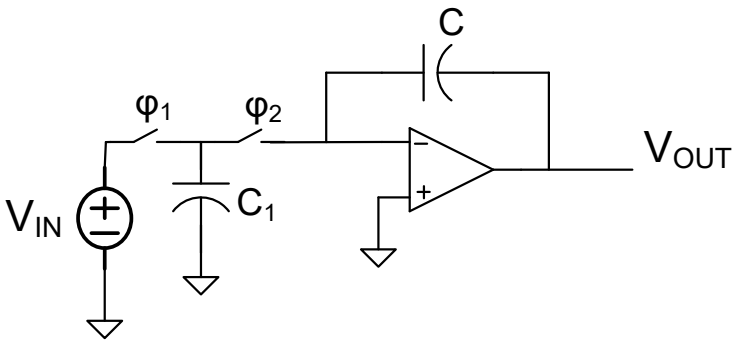
$$Q_{SC} \simeq C_1 V_{in}(t_1)$$

Observe that the SC circuit also transfers charge proportional to V_{in} in short intervals of length T_{CLK}



$$T(s) = -\frac{1}{RCs}$$

$$I_0 = \frac{1}{RC}$$



Comparing the two circuits

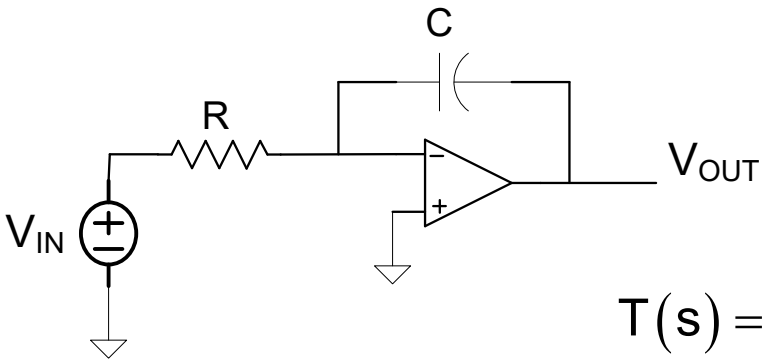
$$Q_{RC} \simeq \left[\frac{V_{in}(t_1)}{R}\right] T_{CLK}$$

$$Q_{SC} \simeq C_1 V_{in}(t_1)$$

Equating charges since both proportional to $V_{in}(t_1)$

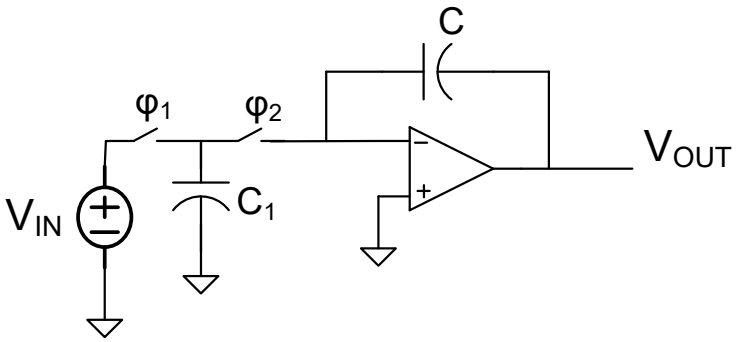
$$C_1 \simeq \left[\frac{1}{R}\right] T_{CLK}$$

$$R_{EQ} \simeq \frac{1}{f_{CLK} C_1}$$



$$T(s) = -\frac{1}{RCs}$$

$$I_0 = \frac{1}{RC}$$



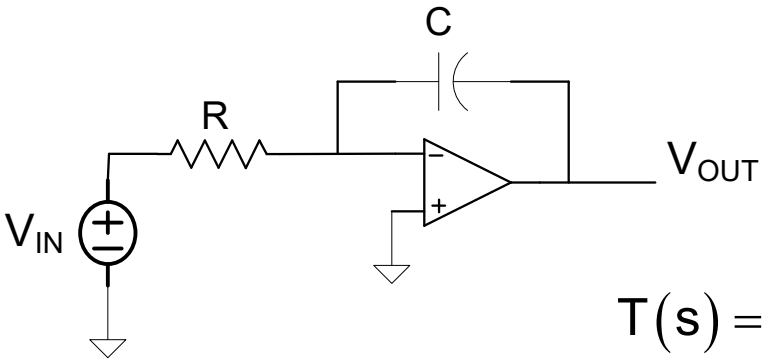
$$R_{EQ} \simeq \frac{1}{f_{CLK} C_1}$$

Observe that a switched-capacitor behaves as a resistor!

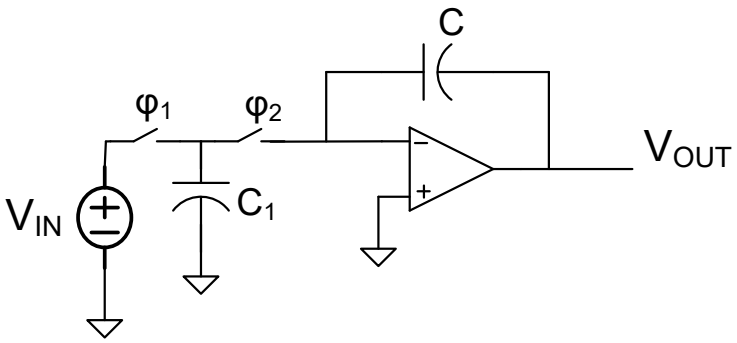
This is an interesting observation that was made by Maxwell over 100 years ago but in and of itself was of almost no consequence

Note that large resistors require small capacitors !

This offers potential for overcoming one of the critical challenges for Implementing integrators on silicon at audio frequencies!



$$T(s) = -\frac{1}{RCs}$$



$$I_0 = \frac{1}{RC}$$

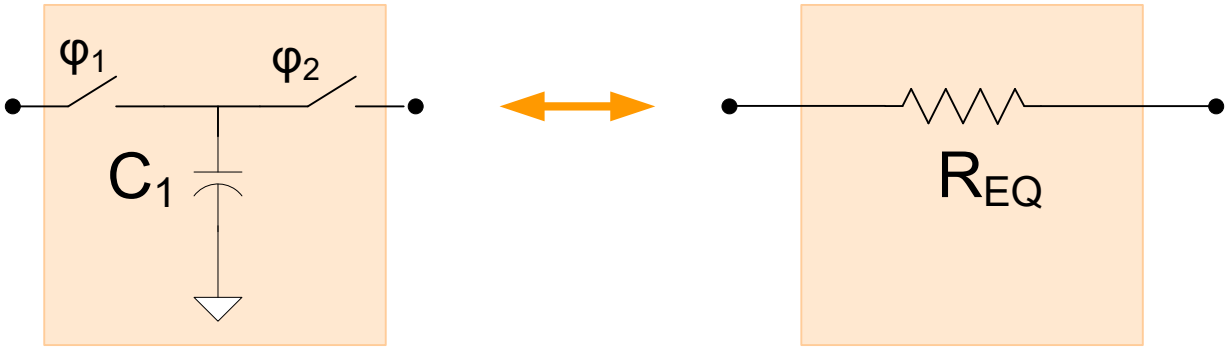
Recall:

1. Accuracy of R and C difficult to accurately control – particularly in integrated applications (often 2 or 3 orders of magnitude to variable)
2. Size of R and C unacceptably large if I_0 is in audio frequency range (2 or 3 orders of magnitude too large)
3. Amplifier GB limits performance

Appears to be Incredible Challenge to Building Filters on Silicon!

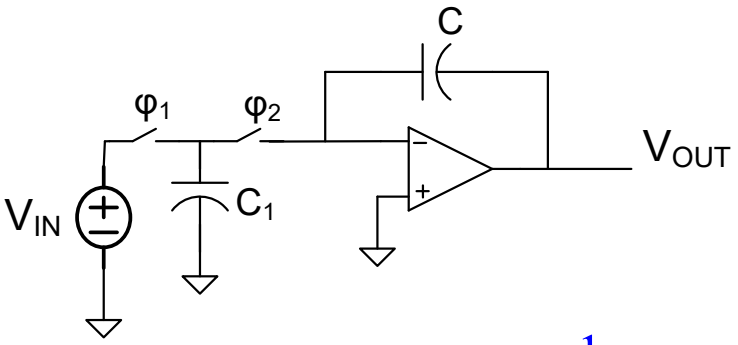
This offers potential for overcoming one of the critical challenges for Implementing integrators on silicon at audio frequencies!

Equivalence Between Rapidly Switched Capacitor and Resistor



$$R_{EQ} \simeq \frac{1}{f_{CLK} C_1}$$

Consider again the SC integrator



$$T_{SC}(s) \simeq \frac{-1}{R_{EQ}Cs} = -\frac{I_{0eq}}{s}$$

$$I_{0eq} = \frac{1}{R_{EQ}C}$$

$$I_{0eq} = \frac{1}{R_{EQ}C} = \frac{C_1 f_{CLK}}{C}$$

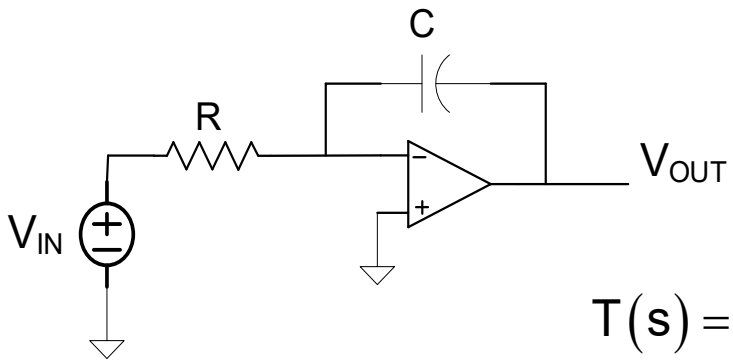
$$I_{0eq} = \left[\frac{C_1}{C}\right] f_{CLK}$$

$$R_{EQ} \simeq \frac{1}{f_{CLK} C_1}$$

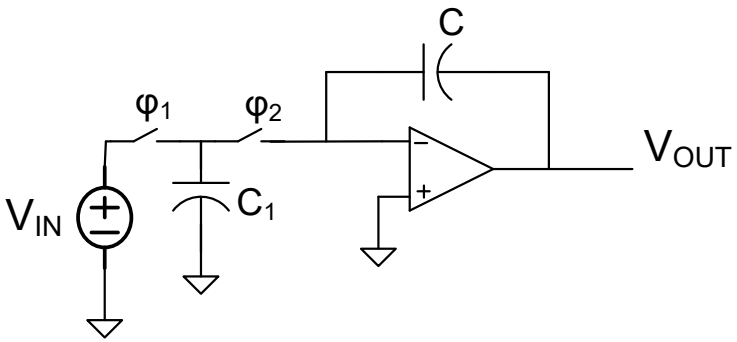
This is a frequency referenced filter!

Note that I0eq can be very accurately controlled !

This offers potential for overcoming one of the critical challenges for Implementing integrators on silicon at audio frequencies!



$$T(s) = -\frac{1}{RCs}$$



$$I_0 = \frac{1}{RC}$$

Recall:

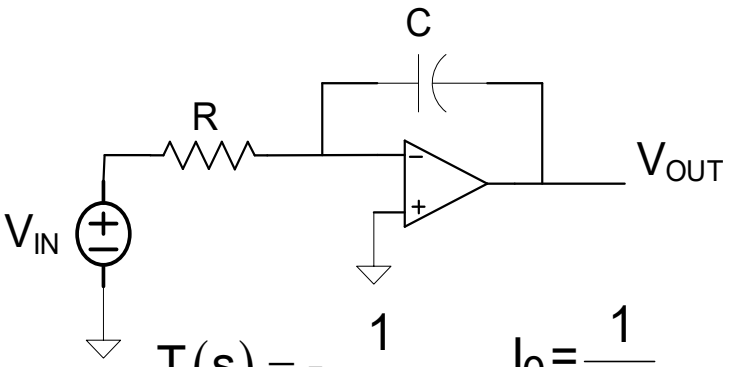
1. Accuracy of R and C difficult to accurately control – particularly in integrated applications (often 2 or 3 orders of magnitude to variable)
2. Size of R and C unacceptably large if I_0 is in audio frequency range (2 or 3 orders of magnitude too large)
3. Amplifier GB limits performance

Appears to be Incredible Challenge to Building Filters on Silicon!

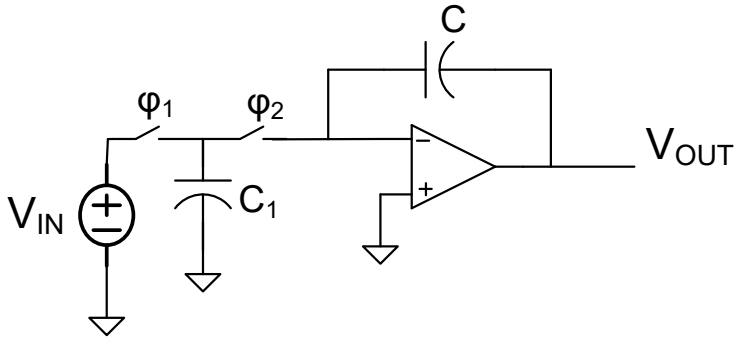
This offers potential for overcoming one of the critical challenges for Implementing integrators on silicon at audio frequencies!

Neither observation by itself was particularly useful but realizing both is really significant!

The Observations about the SC integrator



$$T(s) = -\frac{1}{RCs} \qquad I_0 = \frac{1}{RC}$$



$$T(s) = -\frac{1}{R_{EQ}Cs}$$

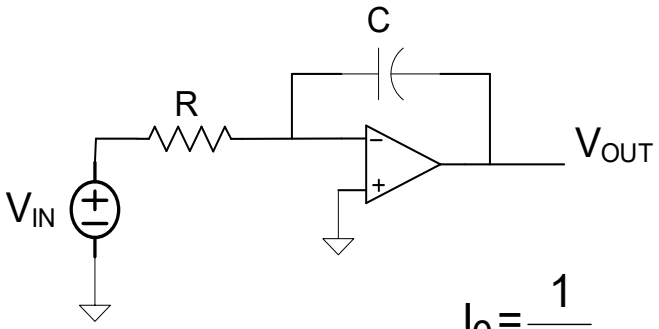
$$R_{EQ} \simeq \frac{1}{f_{CLK}C_1}$$

$$I_{0eq} = \left[\frac{C_1}{C}\right] f_{CLK}$$

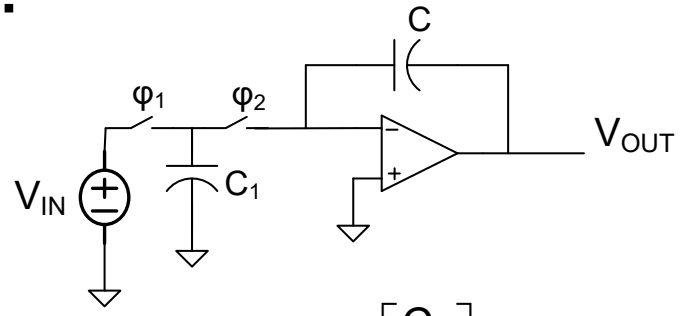
1. **Accuracy of R and C difficult to accurately control (often 2 or 3 orders of magnitude to variable)**
2. **Area of R and C too large in audio frequency range (2 or 3 orders of magnitude too large)**
3. **Amplifier GB limits performance**

1. **Accuracy of cap ratio and f_{CLK} very good**
2. **Area of C1 and C not too large**
3. **Amplifier GB limits performance less**

The Genius !!



$$I_0 = \frac{1}{RC}$$



$$I_{0eq} = \left[\frac{C_1}{C}\right] f_{CLK}$$

1. **Accuracy of R and C difficult to accurately control (often 2 or 3 orders of magnitude to variable)**
2. **Area of R and C too large in audio frequency range (2 or 3 orders of magnitude too large)**
3. **Amplifier GB limits performance**

1. **Accuracy of cap ratio and f_{CLK} very good**
2. **Area of C1 and C not too large**
3. **Amplifier GB limits performance less**

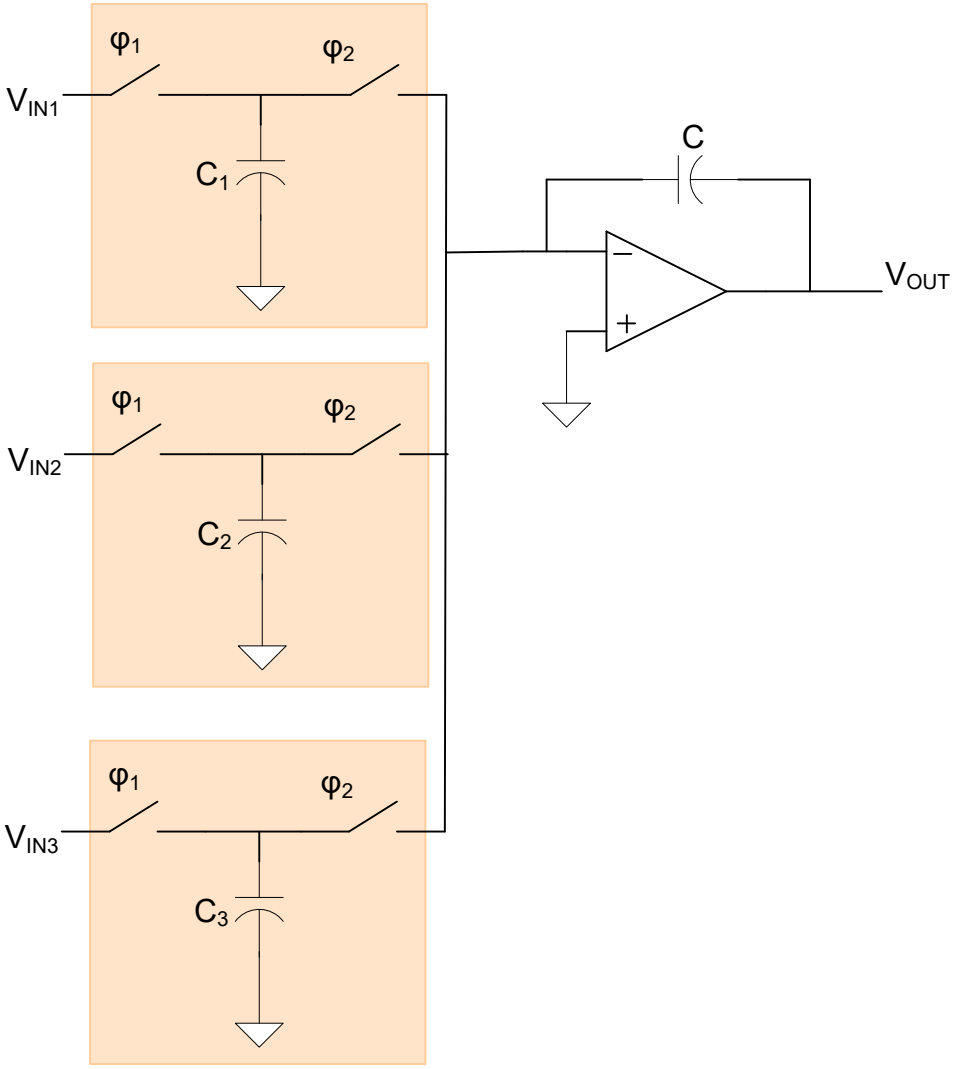
Observation of Maxwell (and other “Me Too” up until 1977) on equivalence of resistor and switched capacitor had no impact

Two groups independently observed items 1) and 2) in 1976/1977 timeframe and realized that practical implementations on silicon were possible and that is the genius of the concept

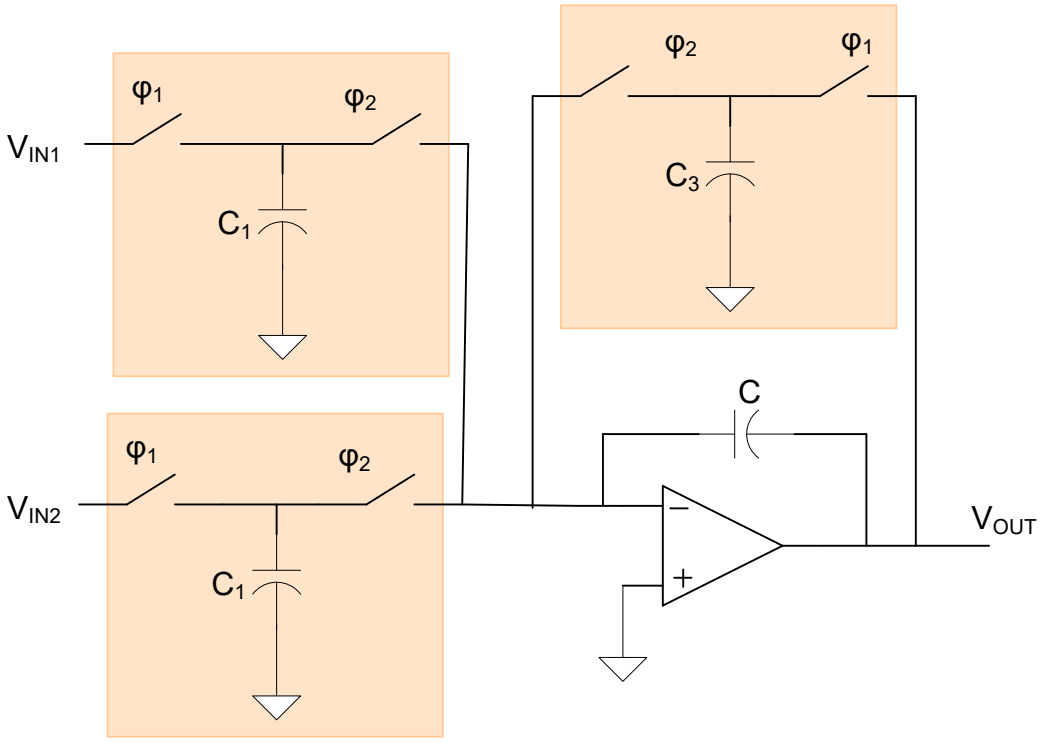
Switched Capacitors and the corresponding charge redistribution circuits now used well beyond the SC filter field

Incredible enthusiasm and effort followed for better part of a decade

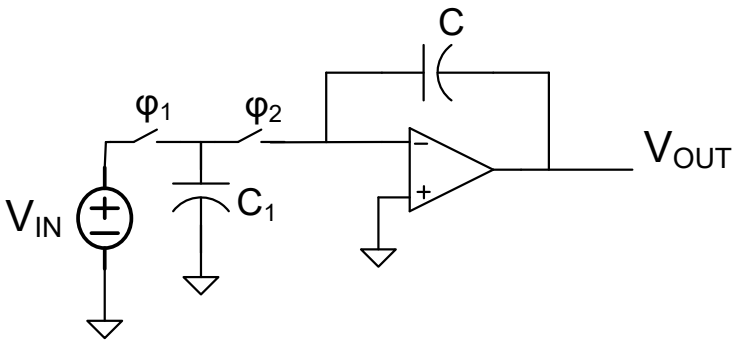
sC integrator with summing inputs



sC low-pass filter with summing inputs

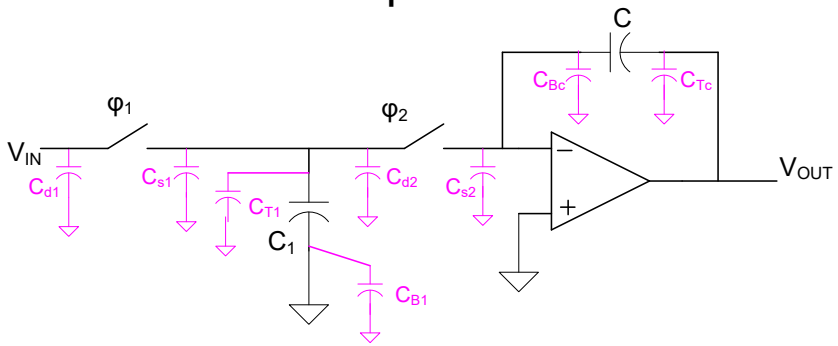


Consider again the SC integrator



$$I_{0eq}=\left[\frac{C_1}{C}\right]f_{CLK}$$

Observe this circuit has considerable parasitics

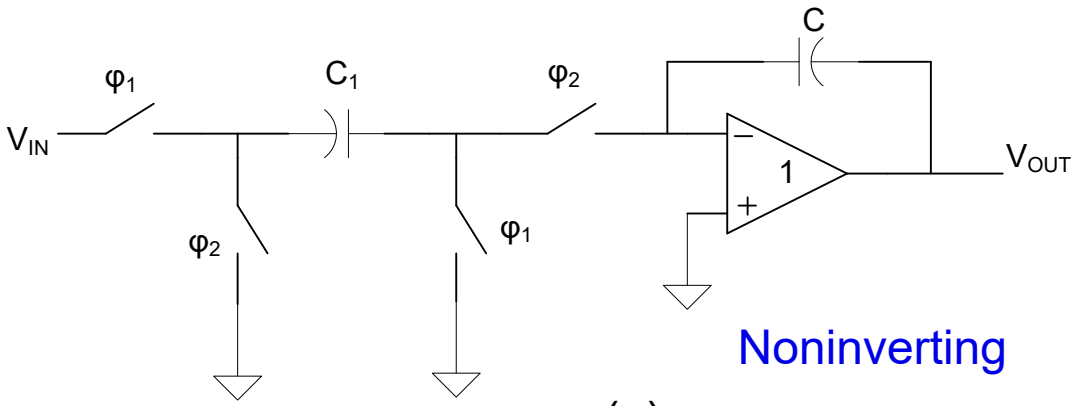


$C_{1EQ}=C_1+C_{s1}+C_{d2}+C_{T1}$

Parasitic capacitors $C_{s1}+C_{d2}+C_{T1}$ difficult to accurately match

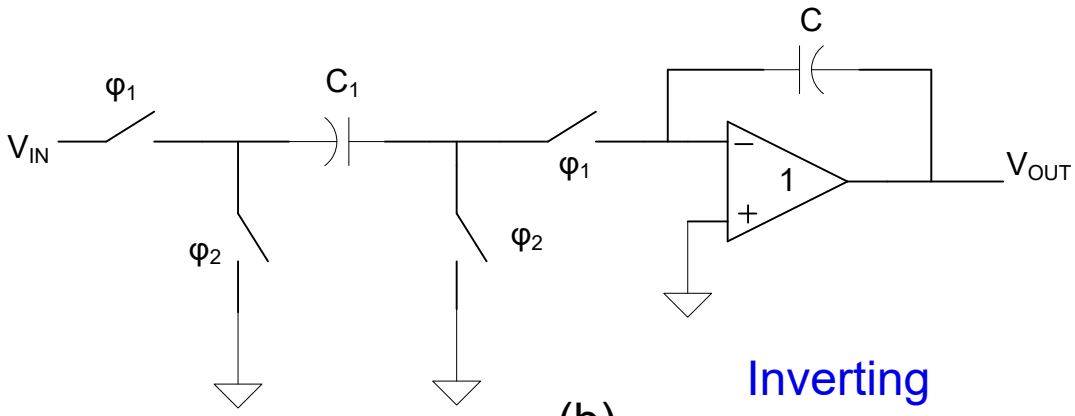
- Parasitic capacitors of THIS SC integrator limits performance
- Other SC integrators (discussed next) ofter same benefits but are not affected by parasitic capacitors

Stray insensitive Inverting and Noninverting SC integrators



Noninverting

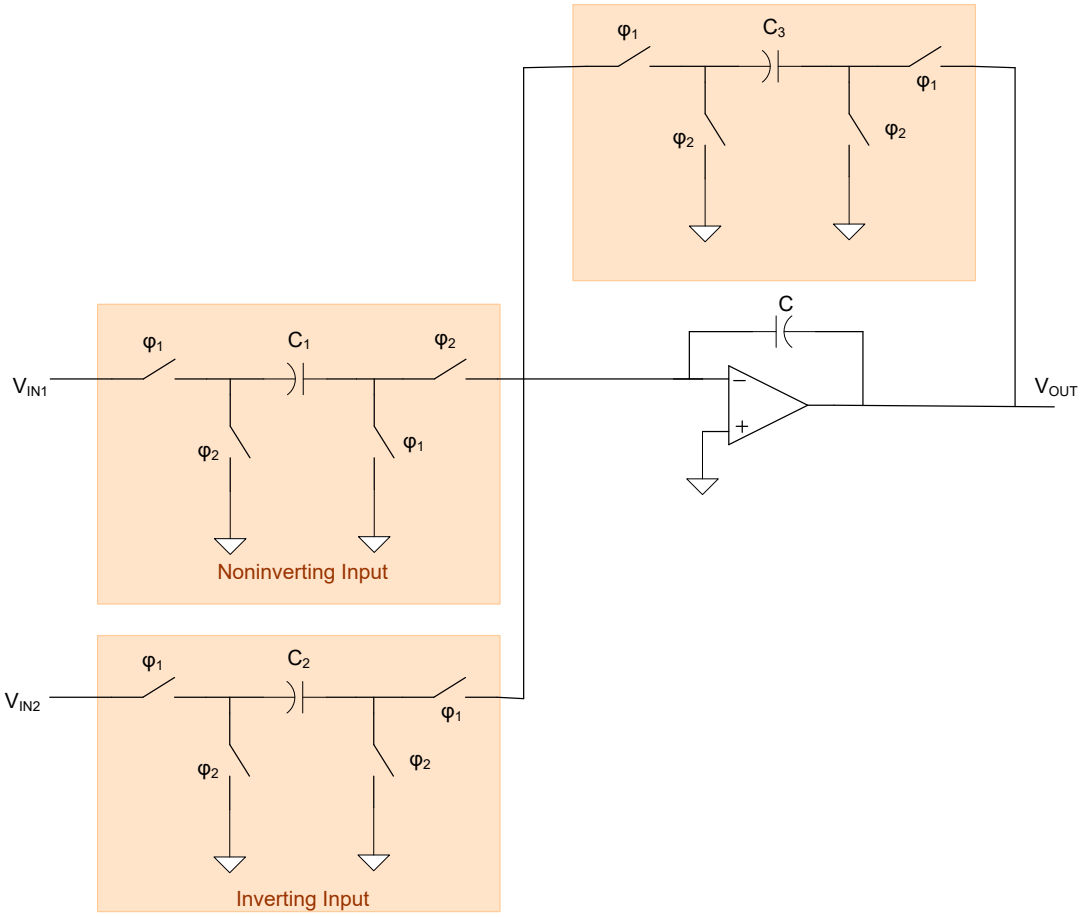
(a)



Inverting

(b)

Stray Insensitive SC Low-Pass Filter with Inverting and Noninverting Inputs

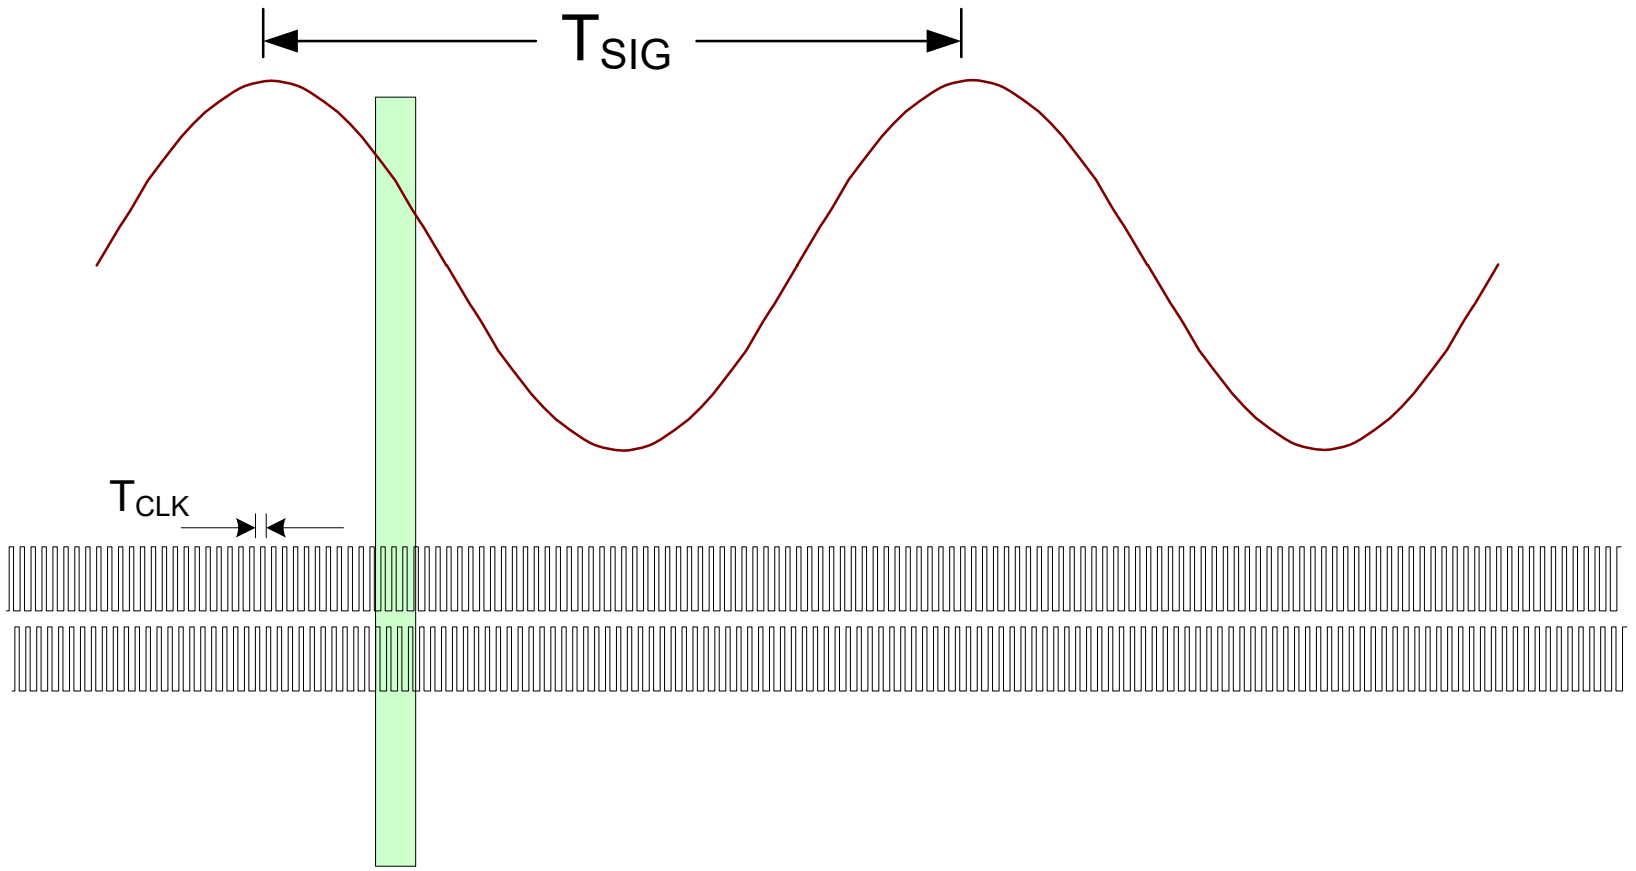


Arbitrary number of inverting and ioninverting Inputs can be added

Switched-Capacitor Filter Issues

What if T_{CLK} is not much-much smaller than T_{SIG}?

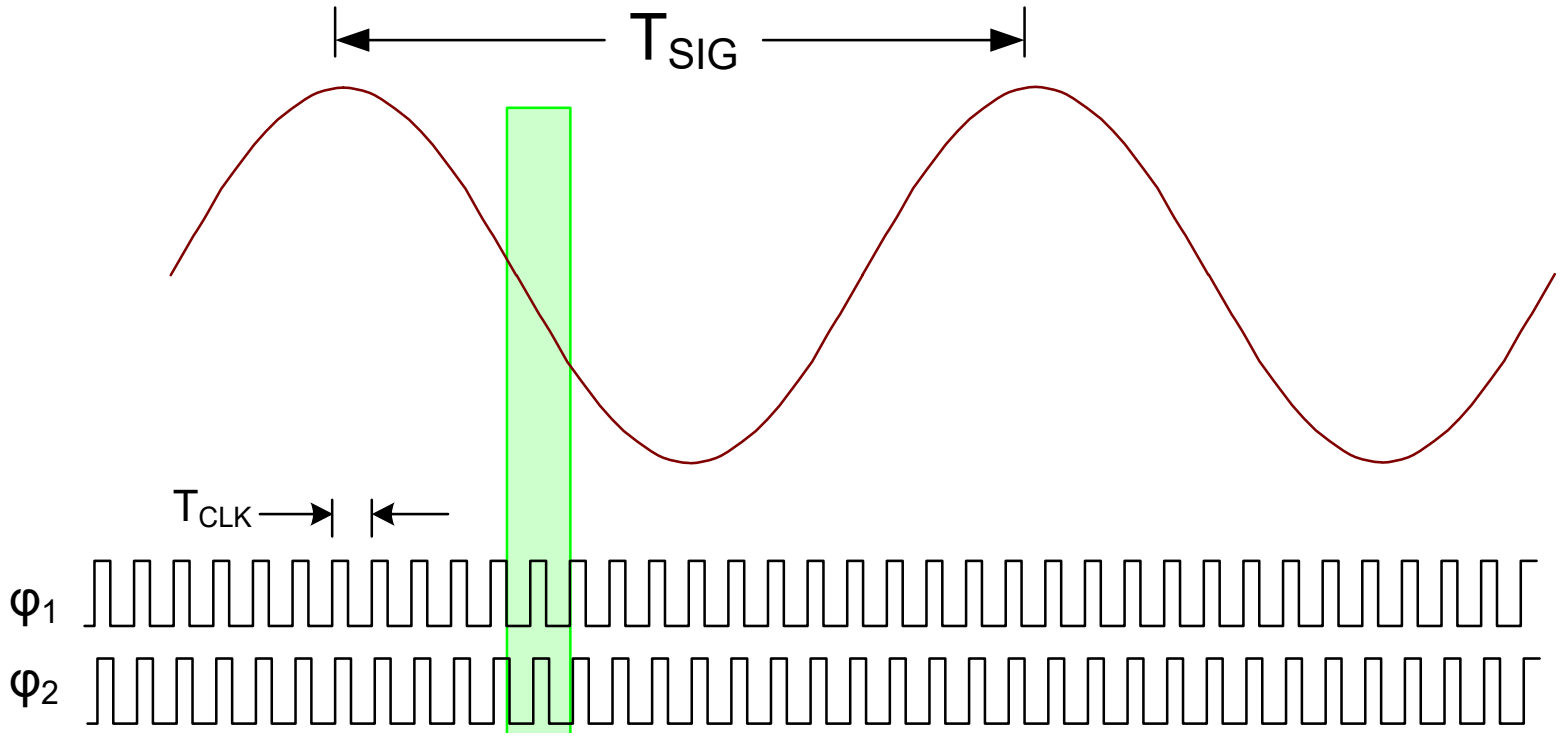
For $T_{CLK} << T_{SIG}$



Switched-Capacitor Filter Issues

What if T_{CLK} is not much-much smaller than T_{SIG}?

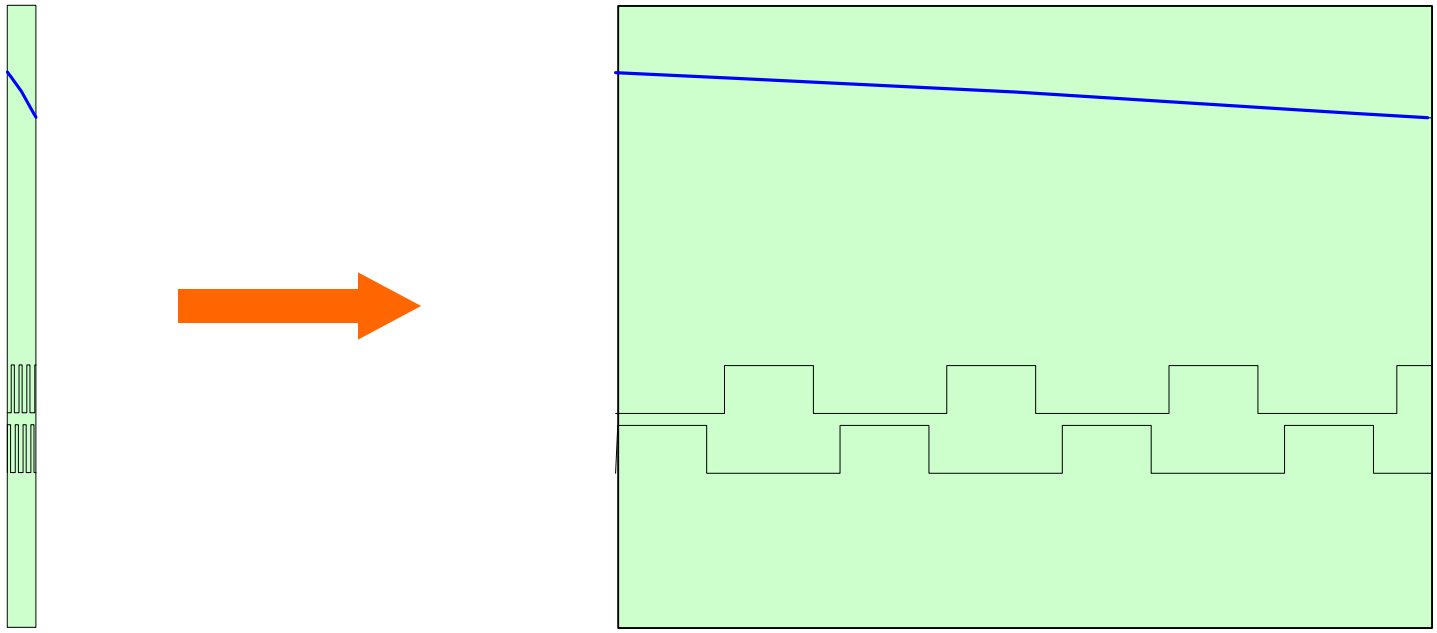
For $T_{CLK} < T_{SIG}$



Switched-Capacitor Filter Issues

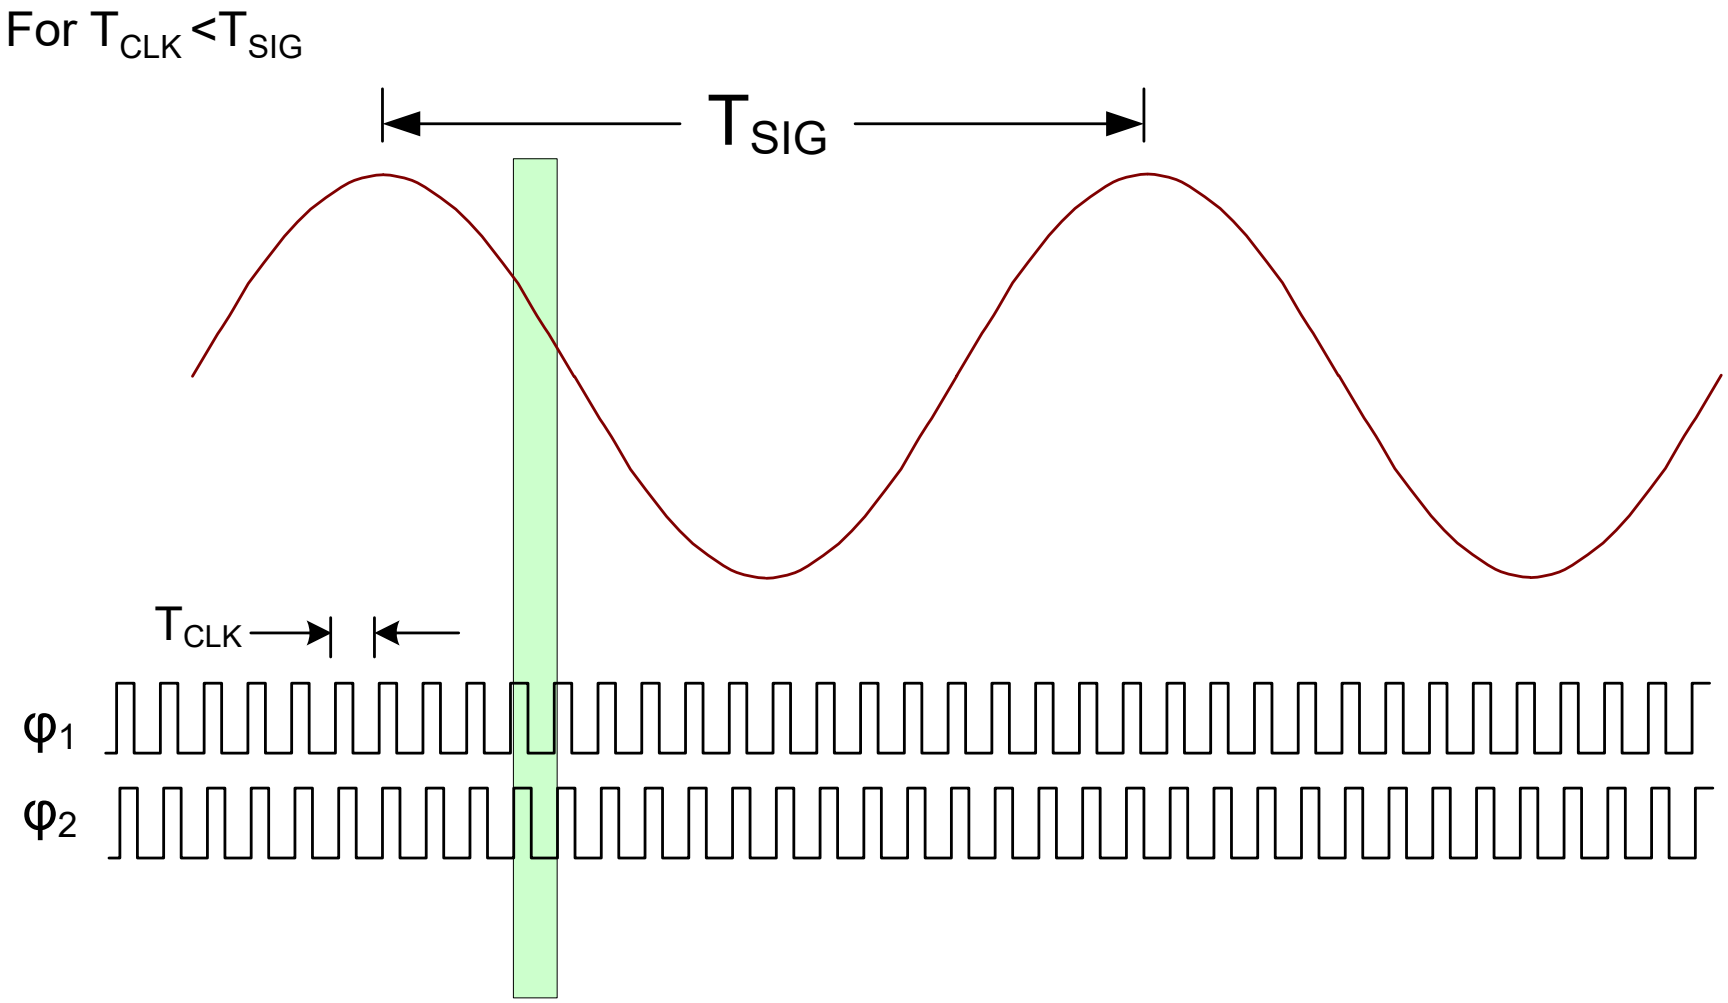
What if T_{CLK} is not much-much smaller than T_{SIG}?

For $T_{CLK} << T_{SIG}$



Switched-Capacitor Filter Issues

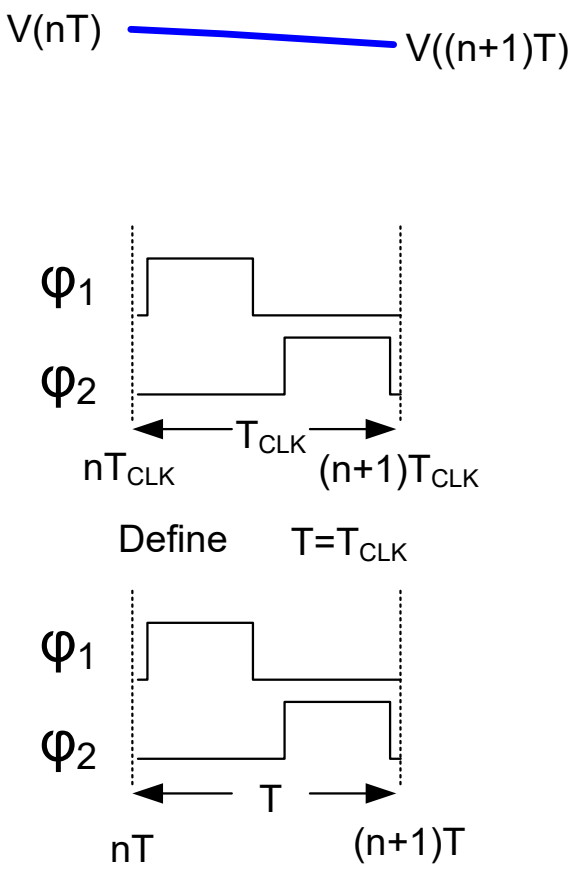
What if T_{CLK} is not much-much smaller than T_{SIG}?



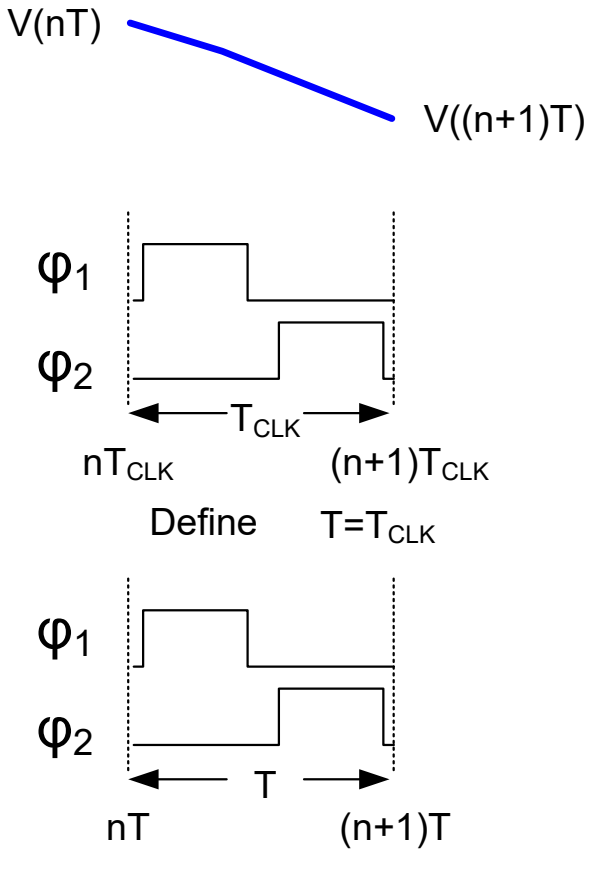
Switched-Capacitor Filter Issues

What if T_{CLK} is not much-much smaller than T_{SIG}?

For $T_{CLK} << T_{SIG}$



For $T_{CLK} < T_{SIG}$

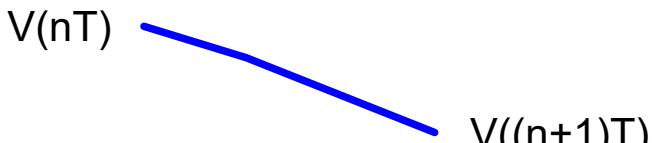


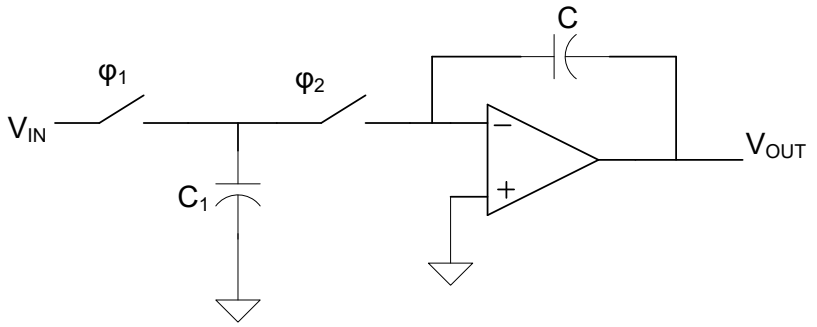
Considerable change in V(t) in clock period

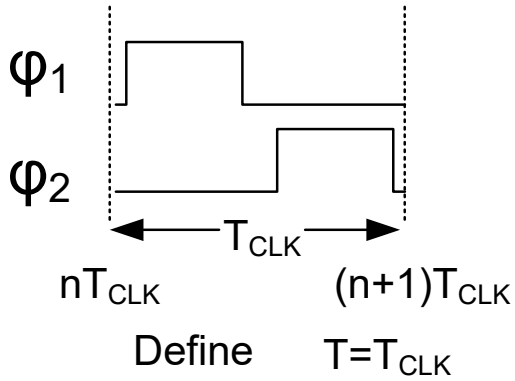
Switched-Capacitor Filter Issues

What if T_{CLK} is not much-much smaller than T_{SIG}?

For $T_{CLK} < T_{SIG}$







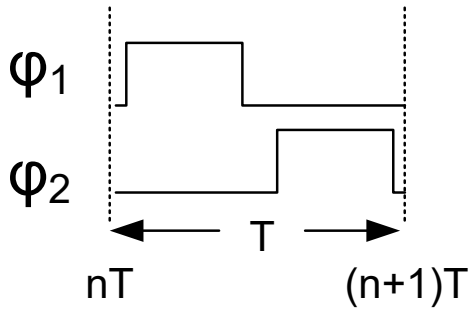
Define $T = T_{CLK}$

$$V_0(nT+T) = V_0(nT) + \frac{\Delta Q}{C}$$

but $-\Delta Q$ is the charge on C_1 at the time φ_1 opens

$$-\Delta Q \simeq C_1 V_{IN}(nT+T/2)$$

$$\therefore V_{OUT}(nT+T) = V_{OUT}(nT) - (C_1/C)V_{IN}(nT+T/2)$$



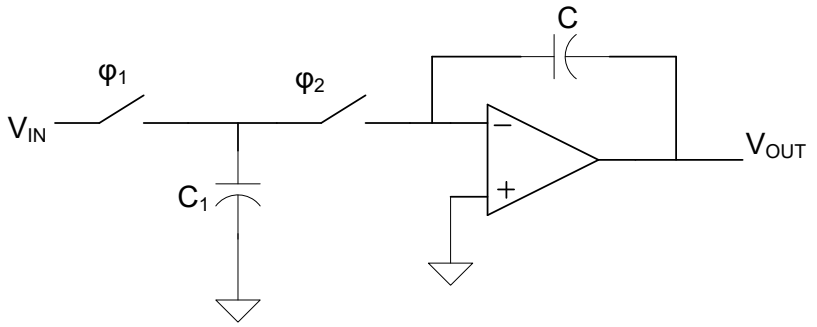
If an input S/H, V_{IN} constant over periods of length T
thus, assume $V_{IN}(nT+T/2) \simeq V_{IN}(nT)$

So obtain

$$V_{OUT}(nT+T) = V_{OUT}(nT) - (C_1/C)V_{IN}(nT)$$

Switched-Capacitor Filter Issues

What if T_{CLK} is not much-much smaller than T_{SIG}?



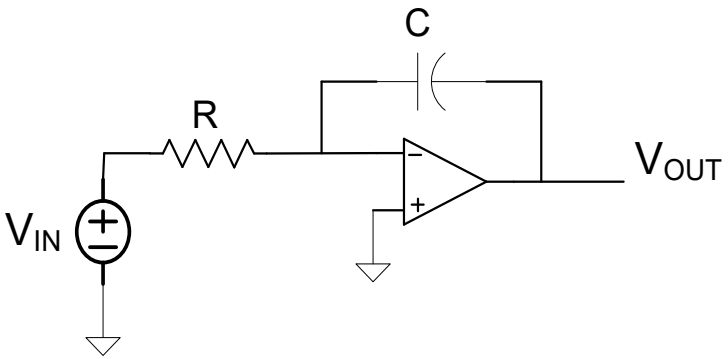
$$V_{OUT}(nT+T)=V_{OUT}(nT)-(C_1/C)V_{IN}(nT)$$

for any T_{CLK}, characterized in time domain by difference equation

or in frequency domain characterized by transfer function obtained by taking z-transform of the difference equation

$$H(z)=-\frac{C_1/C}{z-1}$$

What is really required for building a filter that has high-performance features?



Frequency domain:

Transfer function

$$T(s)=\frac{1}{RCs}$$

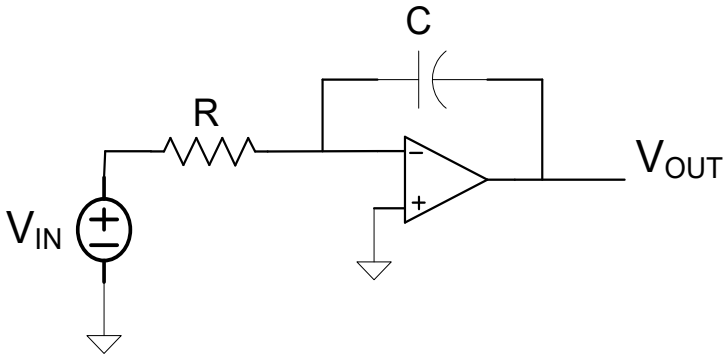
Time domain:

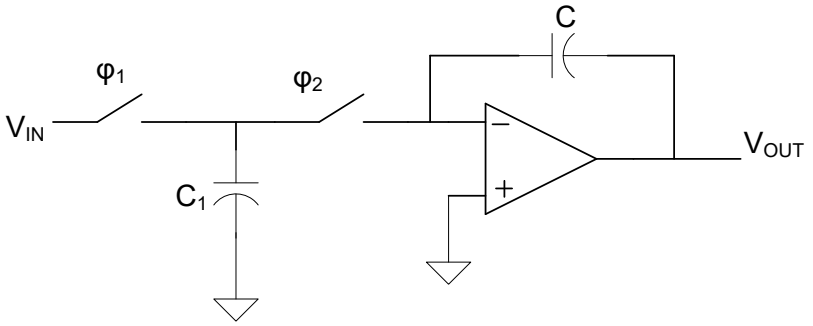
Differential Equation

$$V_{OUT}(t)=V_{OUT}(t_0)+\frac{1}{RC}\int_{t_0}^{t}V_{IN}(\tau)d\tau$$

Accurate control of polynomial coefficients in transfer function or accurate control of coefficients in the differential equation

What is really required for building a filter that has high-performance features?





Frequency domain:

Transfer function

$$T(s)=\frac{1}{RCs}$$

$$H(z)=-\frac{C_1/C}{z-1}$$

Time domain:

Differential Equation

$$V_{OUT}(t)=V_{OUT}(t_0)+\frac{1}{RC}\int_{t_0}^{t} V_{IN}(\tau)\,d\tau$$

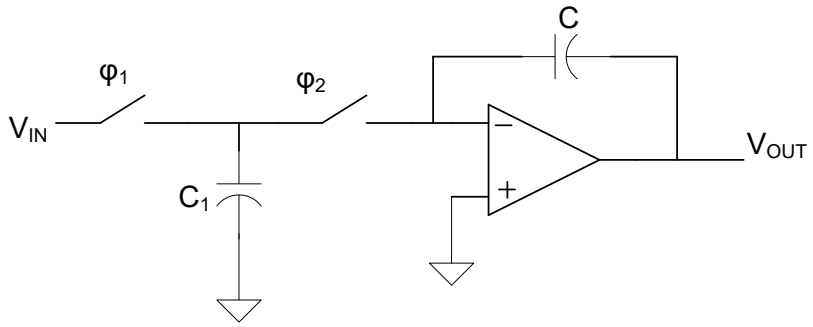
Difference Equation

$$V_{OUT}(nT+T)=V_{OUT}(nT)-(C_1/C)V_{IN}(nT)$$

Accurate control of polynomial coefficients in transfer function or accurate control of coefficients in the differential/difference equation

Switched-Capacitor Filter Issues

What if T_{CLK} is not much-much smaller than T_{SIG}?



$$V_{OUT}(nT+T)=V_{OUT}(nT)-(C_1/C)V_{IN}(nT)$$

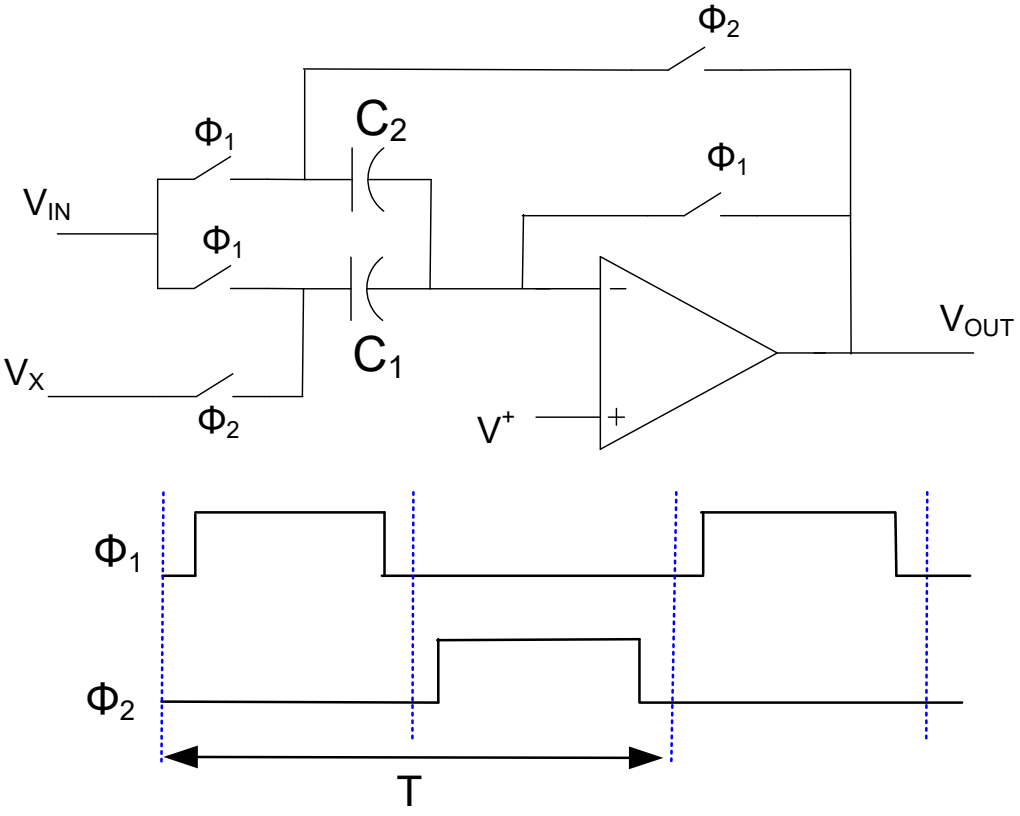
$$H(z)=-\frac{C_1/C}{z-1}$$

Switched-capacitor circuits have potential for good accuracy and attractive area irrespective of how T_{CLK} relates to T_{SIG}

But good layout techniques and appropriate area need to be allocated to realize this potential !

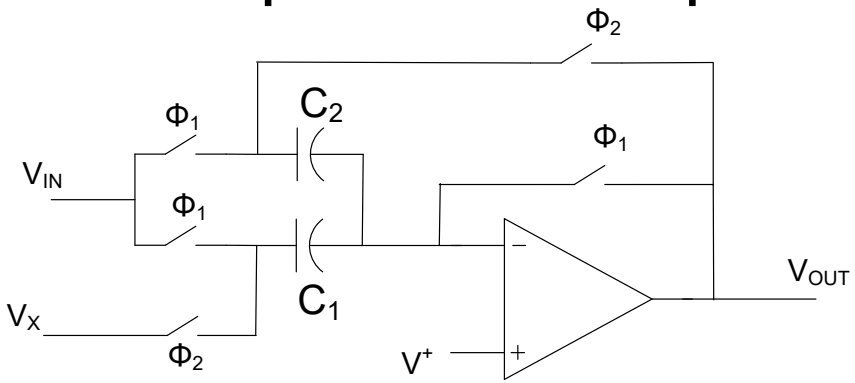
Consider the following circuit

Termed a flip-around amplifier

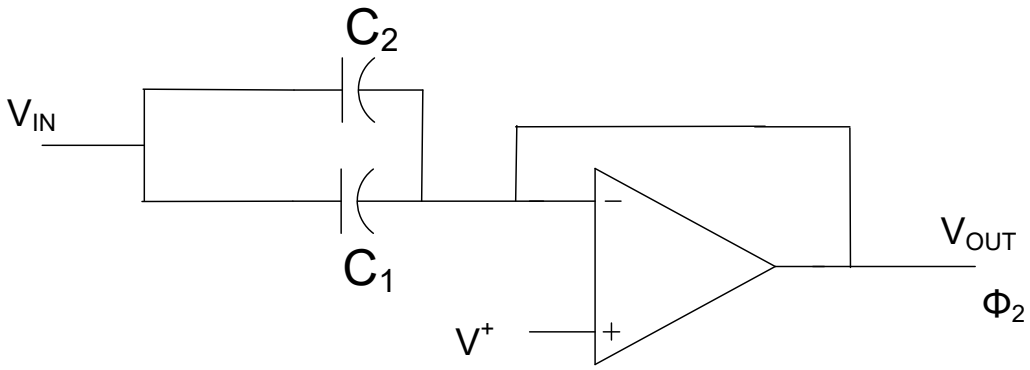


Clock signals are complimentary non-overlapping

The flip-around amplifier

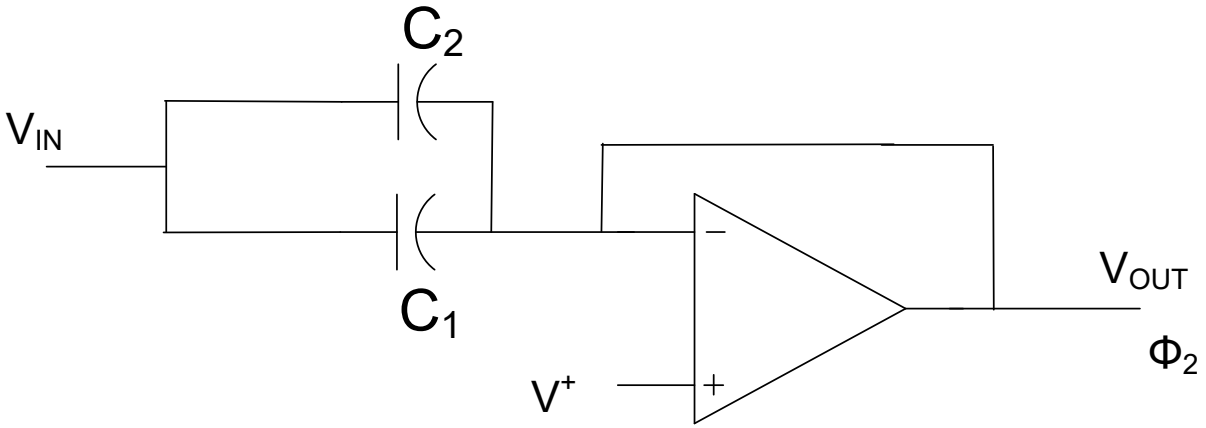


During Φ_1



The flip-around amplifier

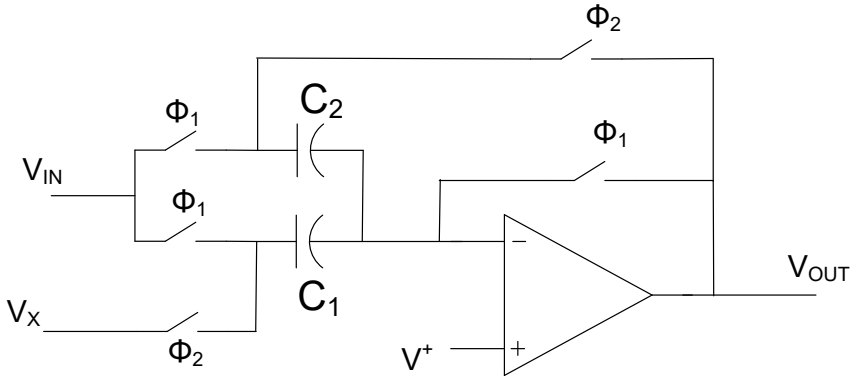
During Φ_1



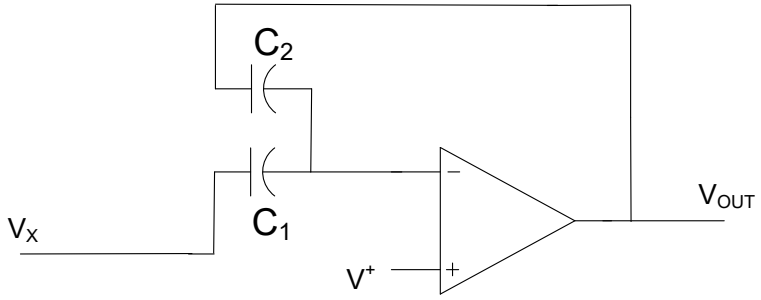
$$Q_1 = C_1\left(V_{IN} - V^+\right)$$

$$Q_2 = C_2\left(V_{IN} - V^+\right)$$

The flip-around amplifier



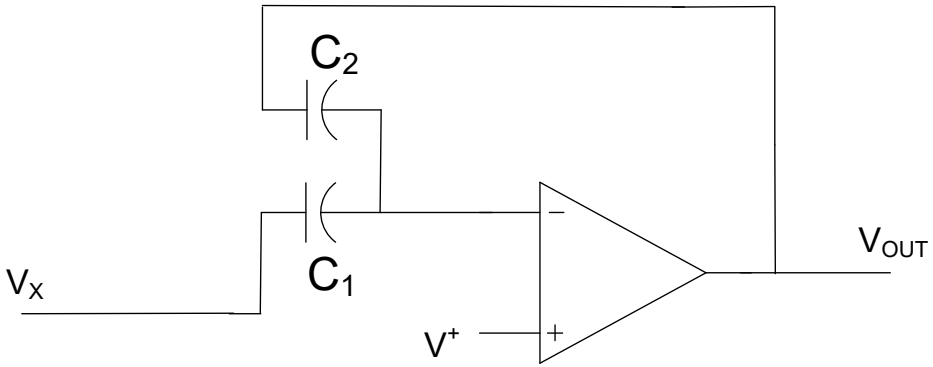
During Φ_2



The flip-around amplifier

During Φ_2

$$Q_1 = C_1\left(V_{IN} - V^+\right)$$
$$Q_2 = C_2\left(V_{IN} - V^+\right)$$

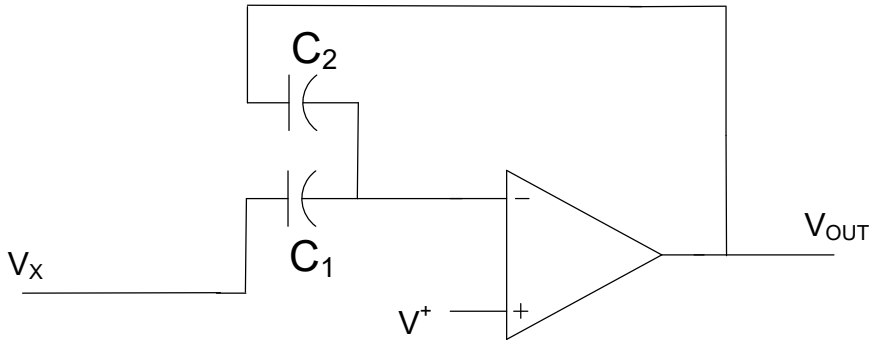


$$Q_{1T} = C_1\left(V_{IN} - V^+\right) - C_1\left(V_X - V^+\right) = C_1\left(V_{IN} - V_X\right)$$

$$Q_{2F} = Q_2 + Q_{1T} = C_2\left(V_{IN} - V^+\right) + C_1\left(V_{IN} - V_X\right) = \left(C_1 + C_2\right)V_{IN} - C_2V^+ - C_1V_X$$

The flip-around amplifier

During Φ_2

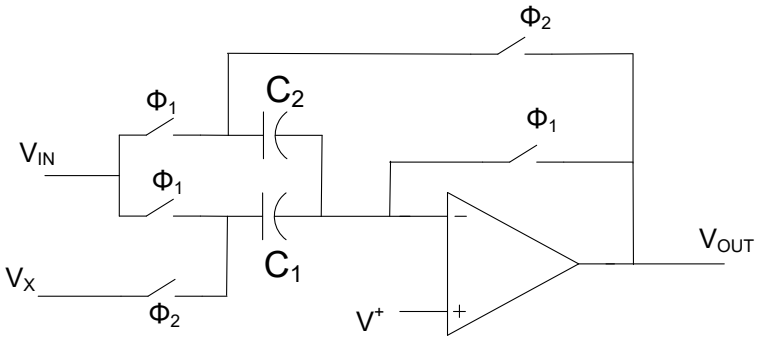


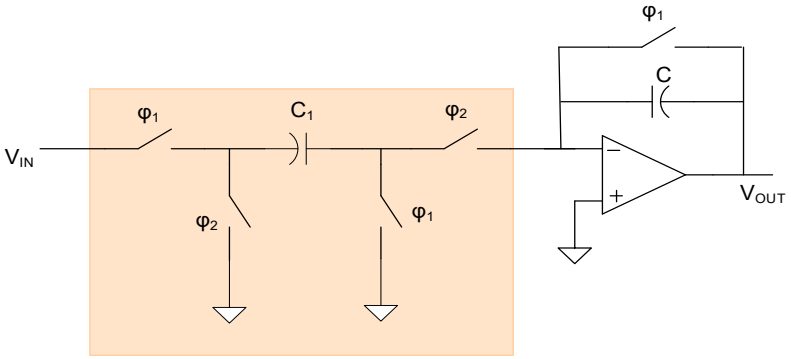
$$Q_{2F} = Q_2 + Q_{1T} = C_2\left(V_{IN} - V^+\right) + C_1\left(V_{IN} - V_X\right) = \left(C_1 + C_2\right)V_{IN} - C_2 V^+ - C_1 V_X$$

$$V_{C2F} = \frac{Q_{2F}}{C_2} = \left(1 + \frac{C_1}{C_2}\right)V_{IN} - V^+ - \frac{C_1}{C_2}V_X$$

$$V_{OUTF} = V_{C2F} + V^+ = \left(1 + \frac{C_1}{C_2}\right)V_{IN} - \frac{C_1}{C_2}V_X$$

Comparison of Flip Around Amplifier with previous SC amplifier





$$V_{OUTF} = \left(1 + \frac{C_1}{C_2}\right) V_{IN} - \frac{C_1}{C_2} V_X$$

$$V_{OUTF} = \frac{C_1}{C_2} V_{IN}$$

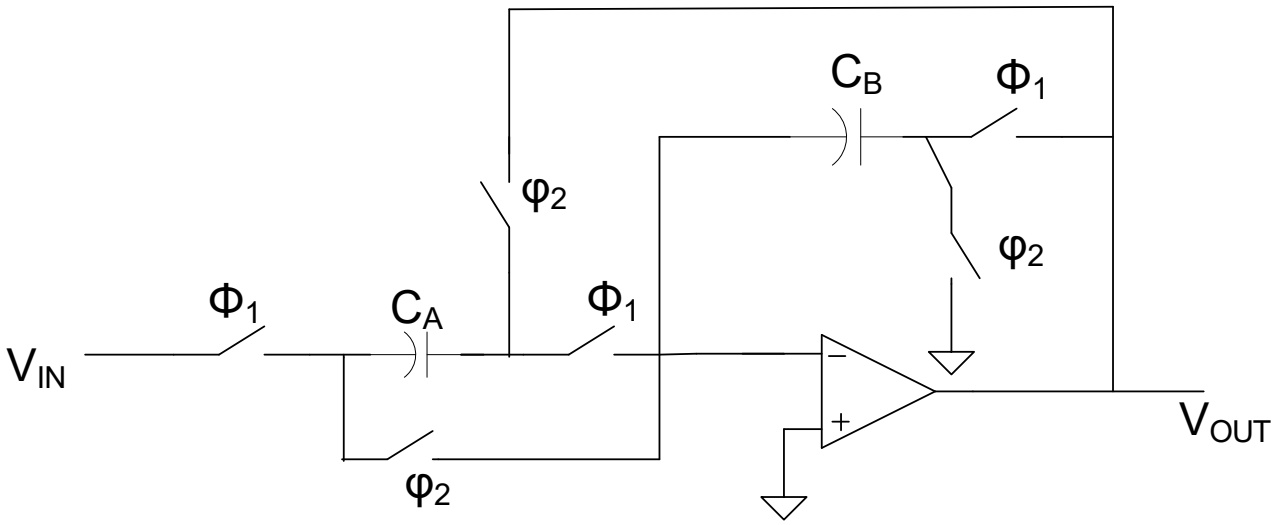
If V_X=0, both have a positive gain but somewhat more gain for a given capacitor ratio for the flip-around structure

In both cases, gain accuracy dependent upon how closely the capacitor ratios can be controlled

One particularly useful application is where want dc gain equal to 2 (1-bit/stage pipeline ADC)

Flip-around requires matching two capacitors, other requires ratio matching of two capacitors

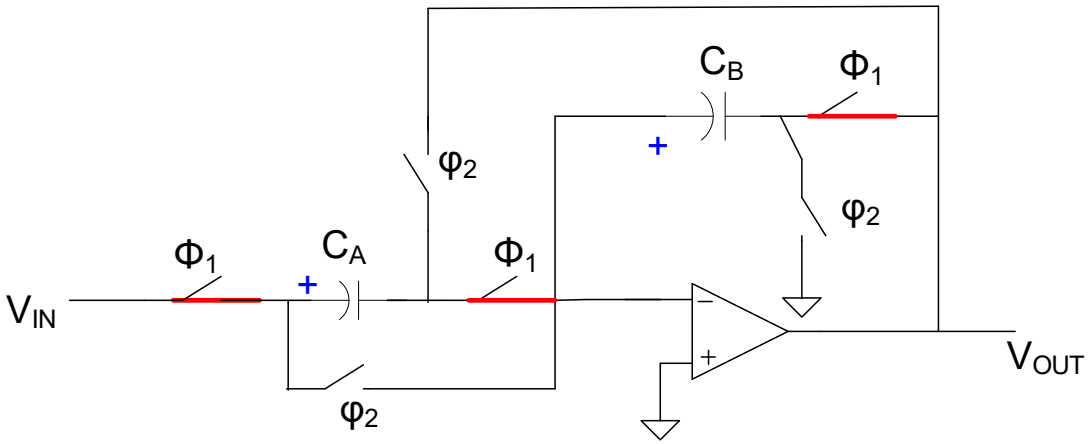
Another Flip Around Amplifier



Clock signals are complimentary non-overlapping

Another Flip Around Amplifier

During phase φ_1



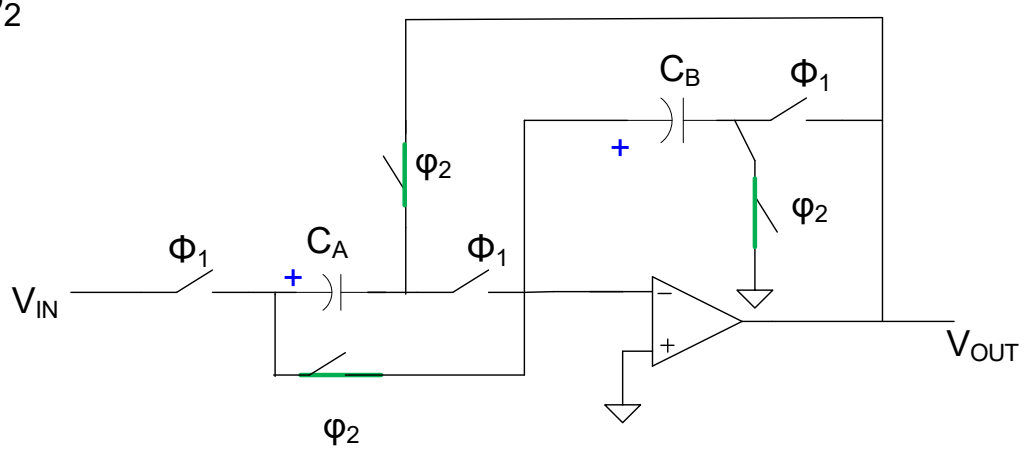
Assume C_B discharged at start of phase – must verify later

$$Q_{CA1} = C_A V_{IN}$$
$$Q_{CB1} = C_A V_{IN}$$

$$V_{OUT} = -\frac{Q_{CB1}}{C_B} = -\frac{C_A}{C_B} V_{IN}$$

Another Flip Around Amplifier

During phase φ_2



From phase φ_1

$$Q_{CA1} = C_A V_{IN}$$
$$Q_{CB1} = C_A V_{IN}$$

$$Q_{CA2} = Q_{CA1} + Q_{CB1}$$
$$Q_{CB2} = 0$$

$$V_{OUT} = -\frac{Q_{CA2}}{C_A}$$

$$V_{CB} = 0$$

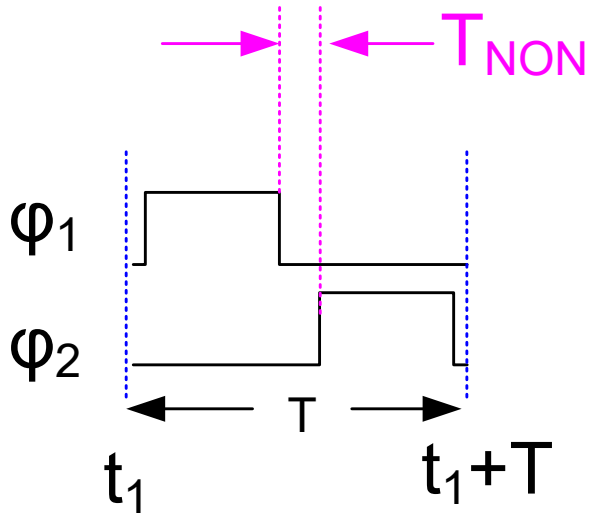
Verified that C_B was discharged at the start of phase φ_1

$$V_{OUT} = -\frac{C_A V_{IN} + C_A V_{IN}}{C_A} = -2V_{IN}$$

This structure has a gain of 2 independent of any capacitor matching!

Can modify to get noninverting gain and gains of 3, 4, .., without matching requirements

Non-overlapping Clocks



- Essential that the clocks be non-overlapping
- Simple inverter to derive the complimentary clock will not work
- Must guarantee non-overlap in the presence of PVT variations
- In non-demanding speed applications, φ_1 and φ_2 will have 25% duty cycles

Stay Safe and Stay Healthy !
